The procedure of tying and incising all the branches of the external carotid on each side seems definitely to have delayed the death of several of the patients in whom it was used. I have used this operation for sarcoma of the antrums and of the tonsil; I have one patient so treated for sarcoma of the antrum living now with the tumor intact, having operated on her in 1913. The starvation method cannot be expected to be of great value when a branch of the ophthalmic artery is aiding in the nourishment of the field.

I have had many cases of orbital sarcomas not here described. The starvation operation is of no value in a carcinomatous condition, for metastasis takes place through the lymphatics.

It is hoped that the general practitioner can be interested to look for the "golden reflex" in children's eyes.

1717 Pacific Avenue.

ABSTRACT OF DISCUSSION

Dr. Edward Stieren, Pittsburgh: I am not in accord with Dr. Morton's statement that melanotic sarcoma of the conjunctiva is not a clinical rarity. To my mind it is one of the rarest of ocular conditions.

I have observed the condition but twice.

In both of these cases the growth arose away from the limbus but reached this region in its extension. Both were confined to the conjunctiva and subconjunctival tissue and had not involved the sclera. I believe the cure in these two cases to be due to the wide excision of the tissues, and to thorough cauterization of their bases. In the first case, with three recurrences, some foci must have been permitted to remain and developed into new growths.

Flat tumors of this nature should be looked on with more suspicion than the more rapidly growing pedunculated growths, the prognosis for recurrence and metastasis being much more favorable in the latter after thorough removal.

I have had no experience with roentgen-ray, fulguration, radium, and thermophore applications, in malignant conditions of the conjunctiva. My feeling is that complete surgical removal would be the best method, eradicating at once all foci of a disease so prone to recurrence and metastasis.

Dr. Walter E. Camp, Minneapolis: Dr. Cary has given clinical reports of twenty-two cases of tumors of the eye and adnexa. Some of these cases were seen twenty-five years or more ago when methods of diagnosis and treatment were much inferior to those employed in more recent years. During the past five years a great deal of confusion has arisen in ophthalmologic literature regarding the nomenclature and origin of intra-ocular tumors. It would seem desirable, for the present at least, until further proof is furnished, that we adhere to the commonly accepted terms applied to these growths. The highly malignant, nonpigmented intra-ocular tumors occurring in infants and young children which have their origin in the retina should be called retinoblastomas (Verhoeff). The less malignant, pigmented (actually or potentially), intra-ocular growths occurring in middle age which have their origin from the uveal tract should be called malignant melanomas, after the terminology of Ewing. This group of tumors comprises the so-called leukosarcoma and melanosarcoma. The question of pigmentation depends solely on differentiation and oxidization. Dr. Cary's plea for the early recognition of intra-ocular tumors is a timely one. The principle of the early recognition of cancer is just as important and as applicable to the eye as to other parts of the body. This is especially true in regard to neuroblastoma, which is highly malignant and can be cured in only a small percentage of cases when recognized early. I feel convinced that Dr. Cary's first case was one of bilateral metastatic retinitis rather than of neuroblastoma. Bilateral neuroblastoma advanced to the stage reported in this case would hardly have responded so readily to irradiation. The question of the efficiency of x-rays and radium after enucleation or exenteration in cases of intra-ocular growths is much debated. In neuroblastoma they have little value except in cases in which the tumor is diagnosed very early.

Dr. Laura A. Lane, Minneapolis: I have been making a study of sarcoma of the eye over a period of eight years, collecting about 530 cases, excluding reports of the past five years, so that the value of other treatments than surgery alone could be ascertained. I have found, since Verhoeff and Loring's report, 77 cases of sarcoma of the conjunctiva in the literature from 1903 to 1925. Three reports were not available. Eighteen of these, including the foregoing, are too meager to use. This leaves 59 cases to study. The number of operations done was 92; number of recurrences, 82; number of metastases, 15; number of deaths, 7; results unknown, 17. Longest period without recurrence or metastasis, 7½ years: one, 5; one, 6; all the others recurred in a much shorter time. The period by years without recurrence, metastasis or death, is interesting. The first year, 11; the second, 7; the third, 2; the fifth, 5; seventh year, 1; ninth year, 1; tenth year, 1; thirteenth year, 1; eighteenth year, 1. During the last fifteen years new forms of treatment, radiotherapy and fulguration, have come into use. It is well to make comparison of the value of these forms of treatment. This study shows that 20 of the 59 patients received radiotherapy; 1 fulguration and cauterization. The number treated by radium alone was 2. One was traced seven years, the other more than twelve years without recurrence or metastasis. The number by operation and radium, 7; by operation and a combination of x-rays and radium, 10; by x-rays alone, 1; by fulguration and cautery 1. Those patients treated by operation and radium, or by operation and radium and x-rays combined were living and well, free from recurrence or metastases, from one to fifteen years later except three. Two of the three were soon lost trace of; the third, aged 81, had had a growth two years and lived two years after the radiotherapy, dying of metastasis. In reference to Dr. Cary's paper: These epitheliomas which occur in the conjunctiva are of considerable importance because the majority recur quickly. Within the past month I have had three cases under treatment—two epitheliomas operated on by good men with recurrence within two years; the other a melanoma. The greater the mitosis, the more rapid the recurrence. That is true of conjunctiva cases and also of other forms of ocular tumor. This problem of cancer is something that ophthalmologists should consider more and more. We must begin to look at it not from the eye alone, but from the problem of the whole body, and we must use biochemical thought in taking up the study of this question.

Dr. S. B. Muncaster, Washington, D. C.: I had a patient, aged 68, who had a melanotic sarcoma of the conjunctiva extending into the inner canthus of the upper lid. The pathologist's report was melanotic sarcoma. I could not get this man back to my office for about ten days, and during that time the growth had greatly increased in size. I sent him to Dr. Augustus Simpson to have x-rays and radium applied, and he told me that the eye would probably suffer from it. I said, "Well, he has cataract anyway and it does not make much difference." He applied the radium three or four times and secured a positive cure. Two years afterward the patient was still free from recurrence.

Dr. E. E. Blaauw, Buffalo: Reliable statistics about the percentage of recidives and metastases are needed. If operation is performed in the first stage of sarcoma, is the prognosis so much better than when the operation is done in the second stage? If these individuals are treated with x-rays and radium I think we should know what they can expect and what we have a right to prescribe for treatment. A metastasis may lie dormant for years, and one can never say a patient is cured; there may be a quiescent stage for ten or fifteen years and still the patient may die of metastasis. The fact that the metastasis may lie dormant so long shows that there is another phase of the subject, which is the localized and perhaps a more generalized immunization. For the further study the immunologist should be called in. In fifty years little has been learned about the value of the different cells as to prognosis. Ophthalmologists do not know when they should operate to the advantage of the patient. They do not know for sure that time is of any value. It may be that there is a very early condition of sarcoma, a small one, and if it is removed one does not know whether good is being done to the patient. It may be that if it is left in a little bit longer there will develop a certain immunization which is rather to the advantage of the patient, because in the first stage the patient may go as fast downhill as when he is operated on in the glaucomatous or second stage. I think that if ophthalmologists will look at that phase of the subject they will get renewed interest.

Dr. William H. Wilder, Chicago: There is one fact in regard to pigmented growths of the skin that should be impressed deeply on the mind of every practicing physician and ophthalmologist, one which has been repeatedly demonstrated by the dermatologists who see more of these cases than we do. They have warned us time and again that in all probability these cases that we call melanoma either of the skin or of the conjunctiva are potentially malignant nevi, which if irritated are apt to spread like wildfire. The first case reported by Dr. Cordes recites such a condition. I remember seeing a similar one, when I was an intern in the Cincinnati General Hospital, reported by Dr. Fall. A pigmented mole on the back that had been irritated furnished a starting point for multiple sarcomatous growths that invaded every part of the body. So rapid was the process that each day many new pigmented growths could be counted on the skin that had not been visible the day before. At autopsy it was found that they had spread to all the organs of the body, the brain, the spinal cord, the eyes and the marrow of the bones. If the initial pigmented growth is on the conjunctiva and usually at the limbus, unless one is prepared to go to the limit of enucleation or even complete exenteration, it should not be excised but given the benefit of all that is best in radium, x-rays, or some form of diathermy.

A case of mine is a remarkable example of what may be accomplished by radium in some of these cases. The case was originally reported before the American Ophthalmological Society, in whose transactions for 1923 a complete report may be found. This woman, aged 41, developed an epibulbar pigmented growth from a small melanoma of the conjunctiva, near the limbus. As the sight of the eye was good she absolutely declined enucleation suggested not only by myself but by Professor Fuchs, Dr. de Schweinitz and others. We decided to use radium. Emanations first tried proved ineffective and the metal was used. By constant treatment not only was the growth gradually dissipated but the abundant pigment scattered through the surrounding conjunctiva and scleral tissue was completely dispelled. When seen within the last three or four months, the eye had a perfectly normal appearance with normal vision.

Dr. F. H. Verhoeff, Boston: Dr. Cary has recorded a large number of tumors. Owing to lack of time, I shall confine my remarks chiefly to the tumors of the optic nerve. It happens that I have had opportunity to study sections of more tumors of the optic nerve than has any one else. I notice that one of the tumors was diagnosed as a neuroma and the other as a fibroma. There is no histologic description so we have nothing to go on except the pictures, and from these I am firmly convinced that neither of the tumors is diagnosed correctly but that they are both gliomas. If I am incorrect in this, then these cases should certainly be recorded at length because they would be the only authentic cases of neuroma and fibroma of the optic nerve in existence. In regard to the operator's anxiety as to whether or not there is a tumor in the eye he has removed, he can remove his anxiety at once by simply taking the eye to the dark room and transilluminating it. In this way the tumor can be seen well, and it is not necessary to mutilate the eye before sending it to the pathologist.

Dr. E. H. Cary, Dallas, Texas: My paper was written from the standpoint of a clinician and, if read in that light, one can understand why certain details were left out. The pathologic specimens of the two cases referred to have fortunately been preserved and are now being exhibited with photomicrographs of three dimensions. The specimens and photomicrographs can be seen in the Scientific Exhibit. I would be glad if the last speaker would go there and look at these specimens and the slides and then let us have the benefit of his opinion. In this connection, I may say that many excellent pathologists have seen the specimens and photomicrographs under discussion and their opinion substantiates anything that may have been said.

SUDDEN DEATH ASSOCIATED WITH BRAIN CYSTS*

LEILA CHARLTON KNOX, M.D.
NEW YORK

Interest in the subject of cerebellar cysts has been greatly stimulated and the knowledge of them has been brought to the attention of American pathologists chiefly because of the monograph of Lindau,[1] which appeared in 1926. The general recognition of the value of this paper has been such that several authors have adopted the designation of "Lindau's disease" to describe the cysts of the cerebellum associated with hemangiomas of the viscera, retina, medulla or cord. Lindau's paper contains a complete survey of 275 cases of cerebellar cysts of various types.

Five cases of brain cyst have been observed post mortem during the course of the last 2,000 consecutive autopsies at St. Luke's Hospital, including only 321 complete examinations of the skull. These probably represent four of the six types recognized in Lindau's classification. The cases may be thus summarized:

Case 1.—A man, aged 32, admitted to the medical ward, April 9, 1915, in the service of Dr. Samuel W. Lambert, complained of headache, vertigo, weakness of the legs and vomiting, of three months' duration. He could not walk without support and tended to fall to the right. The headache was occipital and left temporofrontal. The knee jerks were exaggerated. There was no clonus nor Babinski reflex. Death occurred, April 21. Examination of the brain showed a cyst about 4 cm. in diameter occupying the left lobe of the cerebellum with smooth, white, transparent lining in no way different from the remainder of the cerebellar tissue. It contained straw-colored fluid. Just beneath it, and in the position of the flocculus cerebelli, was a small, discrete, vascular tumor about 2 cm. in diameter. The lateral ventricles showed moderate internal hydrocephalus. Sections of the tumor showed that it was composed of a vascular mass of neoplastic gliomatous tissue with large spindle-shaped or polymorphous nuclei, embedded in a scanty neurogliar reticulum (fig. 1). The blood vessels were fairly thick-walled, and the tumor cells tended to grow best in their vicinity (fig. 2). *This tumor extended only up to the surface of the cyst and did not protrude into it.*

* Read before the Section on Pathology and Physiology at the Eighty-First Annual Session of the American Medical Association, Detroit, June 26, 1930.

[1] Lindau, Arvid: Acta path. et microbiol. Scandinav., 1926, supp. 1, pp. 1-128.

The diagnosis was glioma cerebelli with adjacent cyst.

Case 2.—A man, aged about 55, entered the examining room of the hospital during the night, complaining of dizziness, vomiting and headache. He was slightly dazed and showed some lack of muscular coordination. During the course of an examination by the intern, he lay down and in a few moments died of respiratory paralysis.

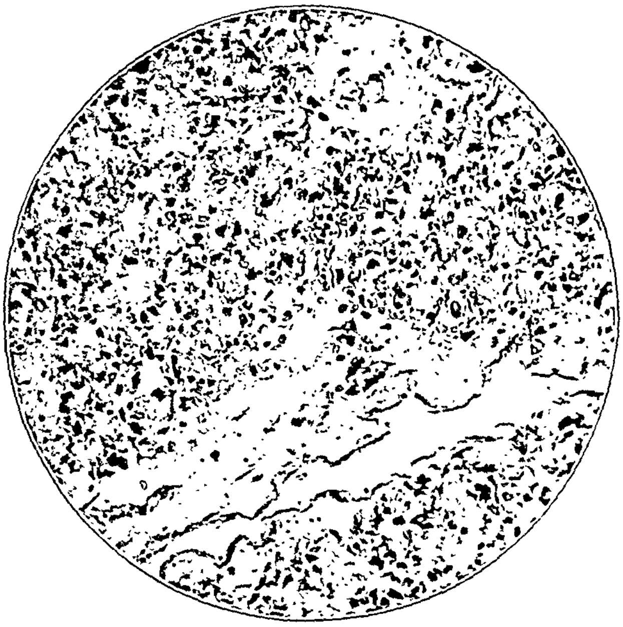

Fig. 1 (case 1).—Glioma in the wall of the cyst; reduced from a photomicrograph with a magnification of 200 diameters.

An autopsy was performed by the medical examiner, and a smooth walled, transparent cyst was found in the right lobe of the cerebellum, with a glistening, white lining, except for one small area about 2 by 1.5 by 1 cm., at which point there was a nodule of small vessels. The fluid was examined for booklets or other evidences of parasites, but none were found. The cyst measured 4 by 3 by 3 cm. and did not connect with the fourth ventricle. There was no meningitis. The microscopic examination of the small nodule showed a vascular mass of tissue containing a few spherical nuclei, regular in form but with poorly defined cell walls. Blood vessels, although very small, formed what may be considered an angiomatous nodule. (fig. 3).

The diagnosis was angioma cerebelli with adjacent cyst.

Case 3.—A man, aged 38, admitted to the medical service, May 17, 1921, in charge of Dr. Samuel W. Lambert, complained of headache, dizziness and disturbance of vision of ten months' duration. In July, 1920, he had suffered from severe frontal headache and pain between the eyes. At the same time his vision became disturbed and he could not recognize colors. He had had slight vertigo and had vomited only once. There was moderate improvement for three months, but one month before admission he became much worse, with one period of partial unconsciousness for from two to three hours. His pulse was 72 and regular. There was a fine fibrillary tremor of his tongue; the knee jerks were equal and active; the abdominal reflexes were present, and there was no Kernig sign nor Babinski reflex. He showed a papilledema of both eyes, with hemorrhages. Death occurred suddenly two weeks after admission with a pulse of 40 and respirations of 12, the patient becoming unconscious only a few moments before death.

Postmortem examination showed that the lingula of the cerebellum was forced down into two tonguelike depressions around the medulla, nearly filling the foramen magnum (fig. 4). More of this tissue extended downward from the right. The right lobe was much larger than the left and was almost entirely converted into a thin-walled cystic cavity containing thin yellow fluid and lined by a white membrane, appearing to be only flattened cerebellar tissue. In one small area, 1 by 0.5 by 0.5 cm., in the inferior and outer wall, was a small pinkish area of tissue resembling granulation tissue. The lateral ventricles were greatly distended and the convolutions flattened. The vessels of the pia arachnoid appeared very small and were nearly empty. The fluid in the cyst gave a negative butyric acid test, did not reduce Benedict's solution, and contained only a few cells having a large nucleus and a large amount of cytoplasm, presumably the pseudoxanthomatous cells of Lindau.

Microscopic examination of the small nodule showed that the lesion was an angioma, probably an hemangioma, as most of the spaces contained red blood cells. The sinuses varied greatly in size; the smaller ones, which closely resembled the cutaneous capillary hemangiomas, were lined with small cells having plump, oval, darkly staining nuclei. The larger sinuses possessed flatter nuclei of the same general appearance. The nodule was fairly cellular with some of the cells apparently lying free in the tissue between the capillaries, as is usually seen in these tumors in infancy (fig. 5). There was a little gliomatous tissue lining the cyst, but no organized cellular or epithelial lining, no necrosis nor degeneration products. A few flattened cortical cells of the cerebellum formed the outer portion of the wall. The other organs showed no lesions of importance, except a small tumor in the spleen 2 cm. in diameter, paler than the surrounding tissue, sharply defined, and with a homogeneous fibrous composition. Section of this showed that it was an angioma with small vascular spaces, smaller than the sinuses of the spleen, but otherwise somewhat resembling them. (fig. 6).

Case 4.—A man, aged 31, admitted, April 18, 1924, to the medical service of Dr. Samuel W. Lambert, complained of dizziness of three weeks' duration, vomiting every half hour for two days, and occipital headache which was relieved somewhat by vomiting. The symptoms had begun three weeks before with great intensity so that he was much prostrated at the end of five days. He had tingling in all his fingers and toes, except the thumbs and first toes. He had been unable to void for twenty-four hours. Neurologic examination elicited a double Kernig sign, nystagmus, increased knee jerks and a left Babinski reflex. Lumbar puncture was done with the removal of 40 cc. of clear fluid under definitely increased pressure. The cellular content, the Wassermann reaction, and the sugar and colloidal gold curve were normal. The patient became comatose four days after admission and died, April 23.

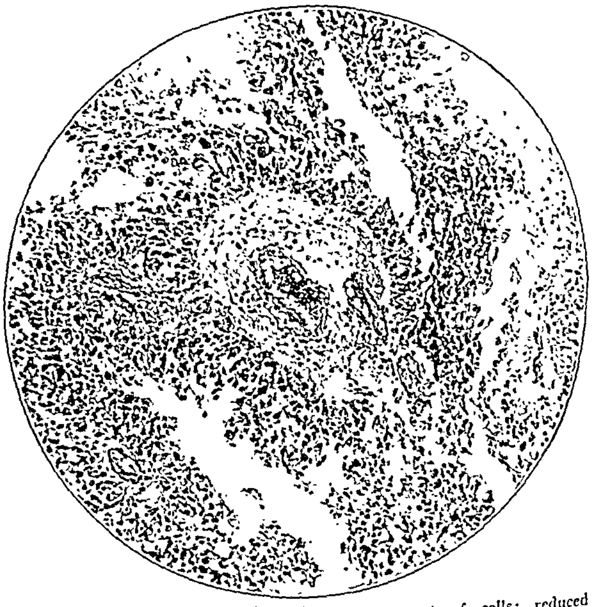

Fig. 2.—Same showing perivascular arrangement of cells; reduced from a photomicrograph with a magnification of 200 diameters.

Autopsy showed that the leptomeninges and the spinal fluid appeared normal, without evidence of infection. The lateral ventricles were slightly distended; the third ventricle much more so. There were no other changes noted in the cerebral hemispheres. The cerebellum showed flattening of the convolutions and on the upper left side a cyst, which was torn in removal with the escape of clear yellow fluid. Section of this showed it to be 5 by 5 by 4 cm., with a delicate, yellowish lining, and a small, soft, vascular area about 1.5 by 1 by 1 cm., protruding from one side into the cavity. The thick gelatinous fluid remained in the neighborhood of the nodule. The aqueduct of Sylvius appeared to have been compressed. Microscopic sections of the nodule in the cyst wall showed a zone of vascular glia in which the vessels were surrounded by a large number of plasma cells and lymphocytes which distended the Virchow-Robin spaces. There were numerous eosinophils and a few polymorphonuclear neutrophils. The intervening cells were mostly glial. Lipoid-containing cells were numerous. There was no indication that these were neoplastic. The lesion in some ways suggested a subsiding infection from the extensive perivascular involvement, but the clear fluid and the thin, nonindurated lining differentiated it from a chronic abscess. On the other hand, it could not be clearly designated an angioma. The absence of pigmentation and of thrombosed vessels excluded hemorrhage. Also the short history and the age of the patient, and the absence of a tumor or parasites, with some evidence of exudation, suggested that we were observing the so-called simple cyst in the period of its formation. Had the patient outlived the early period of high intracranial pressure, it seems probable that a lesion of this type would have been converted into a simple cyst (fig. 7).

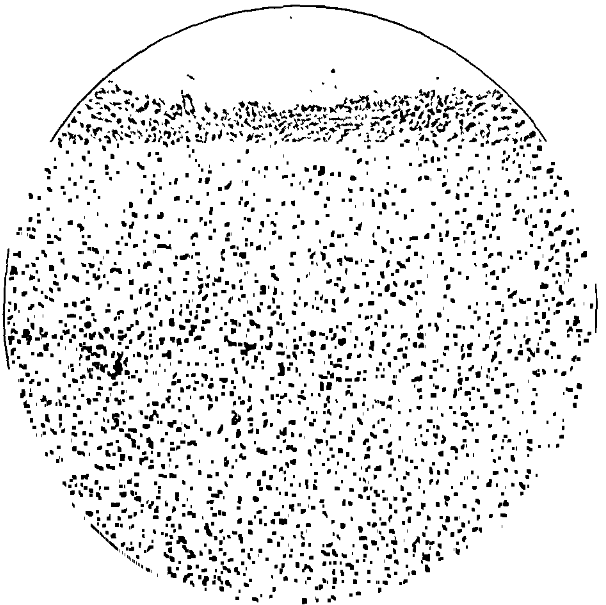

Fig. 3 (case 2).—Cellular area in the wall of the cyst, showing vascular glia with some spherical nuclei, probably phagocytic cells; reduced from a photomicrograph with a magnification of 200 diameters.

The diagnosis was a simple cyst of the cerebellum, of unknown etiology.

CASE 5.—A man, aged 57, who entered the examining room of the hospital at 4 a. m., Nov. 13, 1925, complained of epigastric pain which had been severe for three hours. He had been working steadily up to this time, and the day before he had applied for a civil service examination but was excluded on account of his age. He had eaten heavily that evening and returned home with an abdominal pain and vomited. His temperature was normal; the blood pressure was 180 systolic and 100 diastolic; the pulse was 90. The heart did not appear to be enlarged. There was no dyspnea nor cyanosis and the lungs appeared normal. After resting a few moments in the office he rose, staggered and fell; his pulse became very weak and alternating and respirations two a minute; he complained of extreme dizziness and died suddenly.

The autopsy, which was done three days later because of legal complications, showed the usual postmortem changes with poor preservation of the tissues. There was a slight depression in the right frontal bone 3 by 2 by 1 cm., and in the right temporal region the dura was adherent to the cortex and leptomeninges and had to be cut away to avoid tearing the brain. Beneath this was a fluctuating, thin-walled cyst torn on removal of the dura, with the escape of clear yellowish fluid, leaving a cavity sharply depressed, beneath and in front of the right insula. The meninges were thickened and opaque, with areas of yellowish brown discoloration apparently due to hemosiderin. The leptomeninges over the entire frontal portion of the right hemisphere showed diffuse yellowish areas of opacity but no fresh exudate or blood. Examination of the cyst on section showed it to extend to within 0.5 cm. of the lateral ventricle, but not to connect with it (fig. 8). The lining was smooth and white; the ventricles were not distended. Microscopic examination of the wall of the cyst showed that it consisted of the flattened and atrophic cortical layers of the cerebrum, but the large ganglion cells were atrophic, and the greater portion of the area was composed of neuroglia with small glial nuclei. There was a very delicate covering membrane, apparently pia, loosely attached to the surface (fig. 9). Section of the blood vessels on the surface showed them to be numerous and thick-walled but not thrombosed nor atheromatous.

The diagnosis was cyst of right temporofrontal cortex, probably congenital. This lesion appeared to be a developmental defect because of the absence of inflammatory or vascular changes within the cerebral cortex, the infrequency of ganglion cells, and the delicate lining of pia which extended into the cyst. The question of interest is whether the thickened and adherent meninges may have included an hemangioma and the bony defect in the frontal bone represented the results of an old trauma. In many respects this resembled the cavernous angioma of the meninges described by Dandy.

The only other development lesion observed post mortem was a hypoplasia of the penis, which was small and somewhat deformed. The kidneys showed a moderate degree of chronic interstitial nephritis and a little dilatation of the tubules between the cortical wedges of tissue. This was not at all advanced and the nephritis did not clinically account for the sudden death nor seem to pathologically. The coronary arteries were rather large and patent and showed no calcification nor thrombi.

It was observed by Lindau that cysts of the cerebrum which were pathogenically dissimilar from those of the cerebellum caused the same clinical syndrome and he designated the cases described by Mills and Fraser,[2] Borchardt,[3] and Hildebrand,[4] which presented fluctuating cysts in the membranes of the cerebrum, as cases of meningitis circumscripta cystica. Case 5 may properly be so designated, but this is a descriptive term rather than an explanation of the etiology and it is better considered a cyst complicated by an angioma of the leptomeninges.

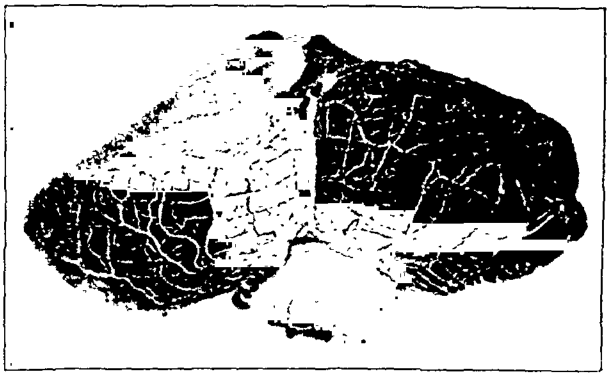

Fig. 4 (case 4).—Posterior aspect of cerebellum and medulla, showing enlarged right lobe and cerebellar tissue surrounding the medulla.

4 Hildebrand, O Arch f klin Chir **100**, 1912

The mode of death of these patients is important from the clinical point of view, as it coincides to a large extent with earlier observations made on patients with cerebral cysts. Lindau cites at least sixteen cases in which sudden death occurred, although it is well known that patients with brain tumors more often than not die a lingering death.[5] Apparently the fluctuations in pressure are greater in cases of cysts than in the case of even the most vascular tumors. A considerable number of patients have died while being prepared for operation; others have been found dead in bed, and several others have died, such as patients 2 and 5, at the time they were being examined for admission to the hospital, while their general condition was still good.

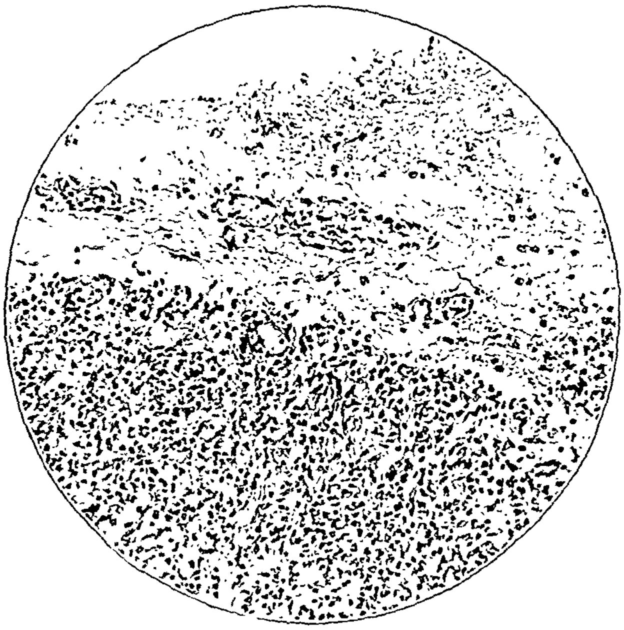

Fig. 5 (case 4).—Hemangioma in the wall of the cyst; reduced from a photomicrograph with a magnification of 200 diameters.

The textbooks of legal medicine do not give much attention to either brain tumors or cysts as a cause of death. The cerebral conditions usually recognized in the nervous system as causes of sudden death are said by Peterson, Haines and Webster[6] to be less frequent than respiratory or cardiac causes. In the nervous system all forms of apoplexy, chronic hemorrhagic pachymeningitis, with or without extensive terminal hemorrhage, acute purulent meningitis, epilepsy, uremia, alcoholism and status lymphaticus, when complicated by epileptical attacks, are the accepted causes, according to these writers. Drennan[7] has reported two interesting medicolegal cases in which death was due to an acute hydrocephalus with edema of the cortex, believed to be due to cysts of the choroid plexus which blocked the third ventricle. These cysts were small, and such as are commonly seen in the lateral ventricle. If more autopsies were done on the brains in cases of sudden death, many of which have previously been assumed to be myocardial, much more information might be obtained on this point. Cysts are, no doubt, a great rarity in any case. Only a few, probably not more than three, of the reported cases have been found as an accidental pathologic discovery in a person dying of lobar pneumonia or some other fatal disease.

Other clinical observations of interest are the variations in pressure on the optic nerve observed in these patients, the first showing only haziness about the disk, the second showing a marked papilledema, and the third, normal fundi, although the cyst in each of these cases was so large as to occupy practically the whole of one cerebellar hemisphere. The compression of the cerebellum around the medulla and in the foramen magnum is also an interesting observation in connection with case 4, but syncope did not immediately follow the lumbar puncture that was performed five days before. Two of the three patients in this series who died suddenly had not been subjected to lumbar puncture.

Lindau recognized six types of cerebellar cysts, as follows:

1. Dermoid cysts and cholesteatomatous cysts.
2. Cysts due to softening, following hemorrhage or malacia.
3. Parasitic cysts.
4. Cysts in connection with a tumor.
5. Simple cysts.
6. Cysts which have a direct connection with the fourth ventricle.

Of the 275 collected cases, Lindau found that they comprised 10 per cent of all cerebellar tumors, and that the majority of them were simple cysts, of the etiology of which he confesses a complete ignorance. Of the dermoid cysts only ten have been reported, and of the parasitic cysts there are also only a few, ten according to Glauberman.[8] Lindau's chief interest centered about the cysts, which were apparently simple but which on investigation were found to contain very small hemangiomas in some portion of the wall and were associated with hemangiomas of the other organs. Lindau showed that these had a tendency to occur in the same families as do the retinal angiomas. Of these he collected twenty-four from the literature and

added sixteen cases of his own. Four of the latter presented also small angiomatous tumors in the medulla; nine of them, multiple visceral angiomas; nine, pancreatic cysts; ten, renal cysts, and six hypernephromas in the suprarenal or kidney. Adenoma of the kidney has also been described but is so frequent that this can hardly be considered more than a coincidence. The following year, 1927, Lindau[9] supplemented his paper by adding reports on two more patients with cerebellar cysts, angiomatous retinas and visceral cystic tumors. He further mentions the cases of Hammer,[10] Rochat[11] and Schuback,[12] which were not included in his first paper.

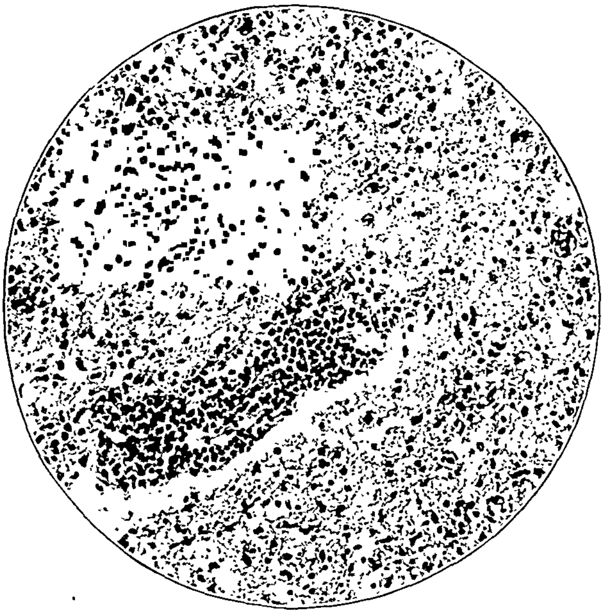

Fig. 7 (case 4).—Cellular tissue, probably inflammatory, found in the wall of the simple cyst; reduced from a photomicrograph with a magnification of 200 diameters.

Angiomatosis of the retina, known as von Hippel's disease, is a form of angiomatosis unrecognized until 1894, when Collins[13] first described the microscopic pathology and designated the lesion as angiomatosis. It was observed in 1895 by von Hippel who, not understanding its nature and finding it as a very minute nodule at the periphery of the retinal field, thought it a chronic inflammatory lesion, possibly a tubercle; but after repeated observation of the patients, he described the condition fully in 1903. Czermak[14] in 1905 also demonstrated the lesion. In all, there have been only a small number of reported cases, and only fourteen of the older ones were examined microscopically. Brandt[15] collected forty of these in 1921 but regarded them as endotheliomas rather than as true hemangiomas. Recently Lindau, Cushing and Dandy have searched assiduously for such lesions in their patients with brain tumors, and Cushing and Bailey[16] have contributed greatly to their recognition. Twenty per cent of the reported cases of von Hippel's disease have presented intracranial complications, but only one of Lindau's cases showed the angiomatous lesion both in the retina and in the cerebellum. The skin angiomas have never been found to be associated with the cerebellar cysts, although they are not infrequently to be found with meningeal angiomas. The latter were collected in 1922 by Lechner,[17] who concluded that many more of them are cerebral than cerebellar, but the knowledge of them has been greatly increased as the result of the surgical pathologic records of Dandy,[18] who has been able to study many of them while they were pulsating and to establish their vascular relations.

The improvement in intracranial surgery brought to clinical importance a knowledge of these lesions, and following the publication of Bruns's paper in 1904 this became an important topic in surgical pathology, whereas before it had had only a pathologic interest.

Sachs,[19] in 1927, reported a case of cystic tumor aspirated in 1920 and again in 1922. Eight months after the second aspiration, 120 cc. of fluid was removed from the cyst, and a tumor was removed from between the cerebellum and the medulla. Although the patient was in coma when operated on, she remained well from October, 1923, to the publication of the paper in 1927.

Schley,[20] in 1927, reported two cases of cerebral angioma, one a subpial tumor of the left cerebral convexity in a patient, aged 52, presenting jacksonian attacks following typhus fever. This formed a cortical cyst 4.4 by 2.5 by 2.5 cm., with smooth reddish brown pigmented walls; also a capillary hemangioma of the cortex of the cerebrum in a patient of 48 who had presented symptoms of manic depressive insanity for ten years. For four months she had had headache and later choked disks, with acute symptoms of increased intracranial pressure for two months; also a cerebellar cyst the size of a hen's egg and without ependymal lining, but with a glioma in the wall. This was a patient, aged 34 years, presenting symptoms of headache, dizziness, ataxic gait and disturbance of vision, increasing for six months.

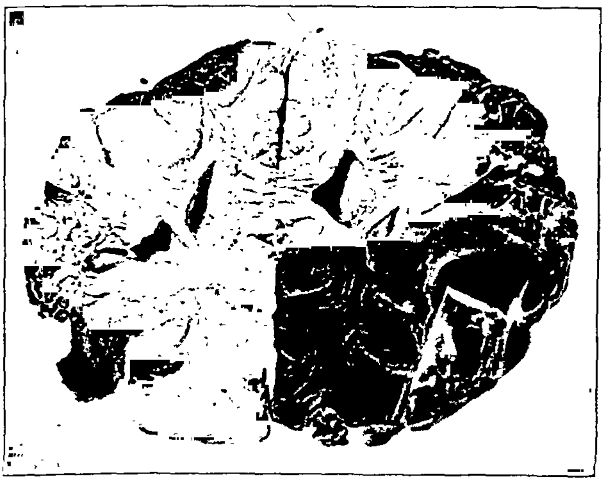

Fig. 8 (case 5).—Cyst showing smooth wall lined with pial membrane.

Cushing, in 1928, described four cases of cerebellar cysts with a small angiomatous mural nodule (cases 18, 19, 20 and 24) and in the same year reported on a sur-

gical patient, aged 30, with von Hippel's disease who had suffered from suboccipital headache for two months with nystagmus, positive Romberg's sign, and an unsteady gait. A cerebellar cyst with xanthochromic fluid and an hemangiomatous tumor nodule in the wall were found. This was successfully removed, and the patient was discharged in a month. Cushing regarded the lesion as even more rare than did Lindau. He has found that the contents of the cysts may resemble blood plasma and believes that an active transudation takes place from the vessels. He found, as the most frequent inaugural symptoms, suboccipital tenderness or discomfort; stiff neck, and headache with vomiting. Ocular symptoms develop much later. This is somewhat in contrast to the frequency of vomiting in cerebellar tumors, which he regards as an early symptom.

Dandy, in 1928, reported six cases of angiomatous cysts of the cerebellum. One of the patients died after operation, one died suddenly on the way to the hospital and four were successfully operated on.

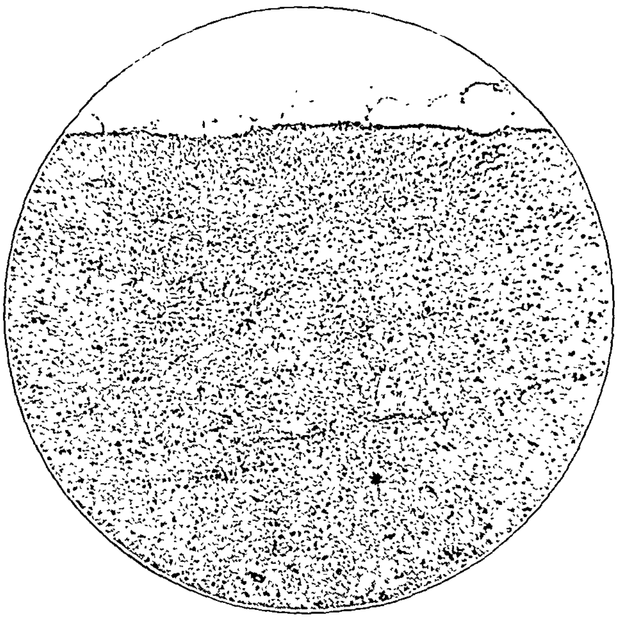

Fig. 9 (case 5).—Cyst showing smooth wall lined with pial membrane; reduced from a photomicrograph with a magnification of 100 diameters.

Glauberman described a simple cyst of the vermis cerebelli in which they have been said never to occur, in a patient, aged 19, seen by him, Feb. 19, 1926. The patient was suffering from headache, ataxic gait, diplopia and choked disks. These symptoms had begun following a severe blow on the head from a heavy pumpkin in October, 1925. He was observed, and repeated lumbar, suboccipital and cisternal punctures were done. A severe, acute meningitis, purulent but aseptic, followed. In August, 1926, he died suddenly with cyanosis, pulmonary edema, enuresis and respiratory paralysis. At autopsy the cerebellum was found to contain a cyst in the lower two thirds of the vermis, 3 cm. in diameter, compressing and narrowing the aqueduct and producing a marked internal hydrocephalus. It did not connect with the fourth ventricle. The wall of the cyst was lined with glial fibers only. The author regarded the cyst as congenital and the meningitis as traumatic in origin.

Sargent and Greenfield.[21] in 1929, described seven angiomatous cysts and two gliomatous cysts. Two of these were successfully operated on and the angiomas removed. One patient who died a year after a decompression was found to have had bilateral angiomatous cysts, one in each of the lateral lobes.

Shapiro's [22] patient, a man, aged 50, showed advanced signs of a cerebellar tumor with mental deterioration and apathy and died of a pulmonary infection. The cyst, when opened, showed the angioma to be relatively large and bulging into the cavity.

Davidoff [23] has contributed one more report of a typical cyst found in a patient who also died a lingering death, with symptoms for two years, and with mental confusion, hallucinations and excitement.

It is therefore apparent that the occurrence of cysts of the brain, cystic tumors, and especially the angiomas, is becoming much better understood. The collected reports of cerebellar cysts number well over 300, and the angiomatous ones alone probably number about 65. They occur most frequently in early adult life, from 20 to 30, but have been seen in patients over 50. Prodromal symptoms have been noted, usually for a comparatively short time, as in several patients who have died before receiving any medical attention. The average duration of such symptoms in the surgical cases has varied from two months to a year and a half. The total duration of the disease untreated or with simple aspiration of the cyst is usually short—often less than a year, or at most two. It is obvious that the neoplastic tumors may not differ in this respect from the simple cysts, since death is usually due to the volume of the fluid and not necessarily to infiltration.

The inaugural symptoms are likely to be headache, suboccipital tenderness, discomfort or stiff neck and slight ataxia, while the later ones are vomiting and others due to pressure on the motor and optic tracts.

The cysts often reach a considerable size, being as large as one lobe of the cerebellum, or larger. Even an experienced pathologist must be careful, in an embalmed body, to differentiate the holes resulting from formaldehyde injection from an antemortem lesion.

The cysts are easily recognized by their thin but definite walls, absence of induration, such as occurs in achronic abscess, and the glistening white lining on which a nodule may or may not be visible. Most of them are in the white matter and do not involve the dentate nucleus. The angiomas, if present, usually occupy the lower, inferior and outer portion. They may be impossible to identify at operation unless they can be felt, and they are so small as to require microscopic examination in some cases.

Trauma has not been shown to have any constant relation to the symptoms or cyst formation, but a few patients have no doubt suffered more headache and stiff neck after a blow on the head or a fall. The other theories as to causation are: congenital, and hence related to syringomyelia; degeneration of a tumor, and transudation of blood plasma from the vessel walls. Only a few have been connected with the fourth ventricle, although this was one of the earliest explanations of their formation.

CONCLUSIONS

1. The present paper is a presentation of the symptoms, course and pathologic observations in four patients with cerebellar and one with a cerebral cyst.

2. Three of these patients died suddenly, having been active up to a short time before death.

[23] Davidoff, L. M.: Am. J. Path. **5**: 141 (March) 1929.

3. The series includes three angiomatous cysts, with an hemangioma of the spleen; one congenital cerebral cyst associated with a cavernous angioma of the leptomeninges, and one gliomatous cyst.

4. Attention is drawn to the fact that such cysts may be present and even be a cause of sudden death in apparently healthy persons.

St. Luke's Hospital.

ABSTRACT OF DISCUSSION

DR. LESLIE T. GAGER, Washington, D. C.: These cases of Dr. Knox especially interest the clinician, who naturally thinks first, if not exclusively, of the more familiar cerebral vascular lesions: embolism, thrombosis and hemorrhage. Two examples of brain cyst have come to my attention in which evidence of intracranial pressure was present during life. In the case of a woman, aged 23, which I mention through the courtesy of Dr. Ralph G. Stillman, there had been headache, pain over the left eye and failing vision for two months. Her gait was unsteady, with a tendency to tilt the head and to fall to the right. There were bilateral choked disks. Attacks of general rigidity of the body occurred, in one of which she stopped breathing. A cyst, 5 cm. in diameter, lined with cells resembling glial cells and containing dark amber clear fluid, was found within the white substance of the left lobe of the cerebellum. Last winter Dr. L. C. Milstead reported to the Washington Society of Pathologists the case of a white woman, aged 24, who was able to drive her automobile to the hospital. She was put to bed and, in the recumbent position, in a few hours' time went into coma and died. Following influenza nine months before, she began to have severe supra-orbital headaches with vomiting, yet an ophthalmologic examination one week before hospital admission, which was for tonsillectomy, was reported negative. For seven hours the unconscious woman was kept alive by artificial respiration. Evidence of constitutional disease was lacking and at necropsy the significant finding was a pedunculated ependymal cyst in the third ventricle, of the size of a cherry. The influence of posture in this patient suggests the importance of localized changes in circulation in the brain as well as, for example, in the conduction system of the heart.

ROENTGEN DIAGNOSIS OF ASCARIASIS*

VINCENT W. ARCHER, M.D.
UNIVERSITY, VA.

AND

CHARLES H. PETERSON, M.D.
ROANOKE, VA.

In September, 1929, during a routine roentgen gastro-intestinal examination of a child, certain signs, described here, were correctly diagnosed as being caused by *Ascaris* in the intestinal tract. This led to a study of the English literature, and no reference to this phenomenon was found, so experimental work was started on a group of children infested with *Ascaris*.

A subsequent search of the foreign literature has revealed several references. Fritz,[1] in 1922, was the first to recognize the roentgen appearance of intestinal ascariasis, using a barium contrast meal. He described two cases. Schinz,[2] in 1924, added another case, while Fritz,[3] in the same year, again reported several additional cases. Busi,[4] in 1924, Giovetti,[5] in 1925, Lapenna,[6] in 1926, and Vietti,[7] in the same year, all reported cases, Vietti having a series of sixty-five. Hugo Laurell,[8] in 1927, covered the entire field of the clinical manifestations of ascariasis in a comprehensive monograph, showing many beautiful films of the barium-filled small intestine with the typical observations described by the former authors. In 1927, Muzii,[9] Vajano[10] and Pansdorf,[11] writing separately, described several cases. Fanardshew,[12] in 1929, reported two.

A brief review of the life cycle of an ascarid will be helpful in understanding the problem. According to Cort, Otto and Spindler,[13] the ova from polluted soil are ingested and hatch in the small intestine. The larvae then migrate through the intestine wall, enter the circulatory system and are carried to the capillaries of the lungs. Here they develop in the air sacs, giving rise to pulmonary changes, pass up the bronchial tree, and are swallowed. After liberation from the lung, about six weeks is required for maturity. A constant supply of fresh larvae is therefore being supplied by the lungs, even after an anthelmintic has cleared the intestinal tract of the parasites. Consequently, to rid a patient completely from *Ascaris* takes considerable time and several courses of treatment.

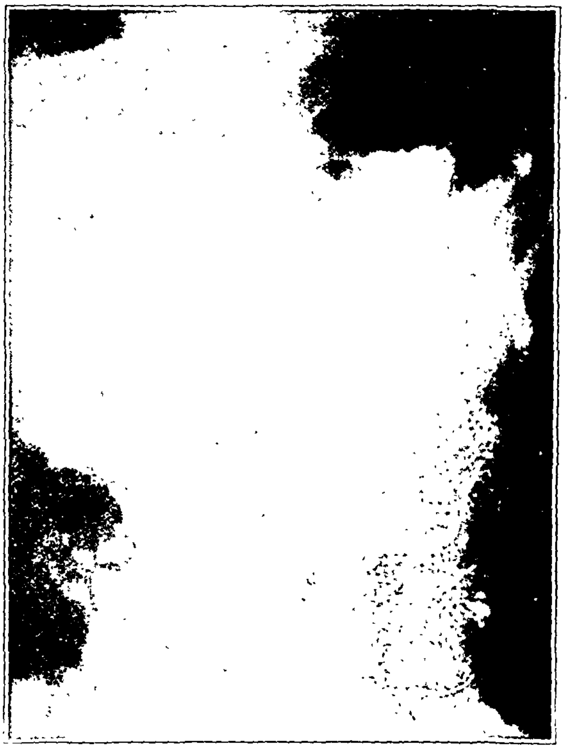

Fig. 1.—Filling defects caused by ascarids in barium-filled jejunum of a child. The film was made immediately after ingestion of a barium cereal meal.

[13] Cort, W. W., Otto, G. F., and Spindler, L. A.: Studies on Ascariasis in Virginia, South. M. J. **22:** 608-614 (July) 1929.

Our interest in ascariasis started with the following case: A boy, aged 13 years, was admitted to the University of Virginia Hospital, Sept. 6, 1929, with a diagnosis of subphrenic abscess. This was cleared up surgically, and after operative recovery, cholecystograms were made and a contrast meal was given in an attempt to find the original focus for the abscess. A nonfunctioning gallbladder was demonstrated. The contrast meal showed a deformed duodenal bulb, interpreted as due to adhesions. On the films, made within a few minutes after ingestion of the barium cereal meal (fig. 1), two long cylindric filling defects were noted in the loops of the jejunum immediately beneath the stomach. At six hours, the contrast meal had passed entirely out of the jejunum, and two long stringlike shadows were seen (fig. 2). A rather hasty search of the literature gave no light as to the nature of these unusual shadows, but after much thought a diagnosis of intestinal ascariasis was made. Repeated stool examinations following this report were negative for ova. On operation for removal of the nonfunctioning gallbladder, the surgeon felt the parasites through the intestinal wall and made them move by pinching them, thus dispelling the last lingering clinical doubt as to the correctness of the roentgen observations. Our interpretation of the filling defect, followed by the stringlike shadows, was that at first the parasite displaced the barium and then ingested some of it, which stayed in the enteric canal of the ascarid after the jejunum had emptied.

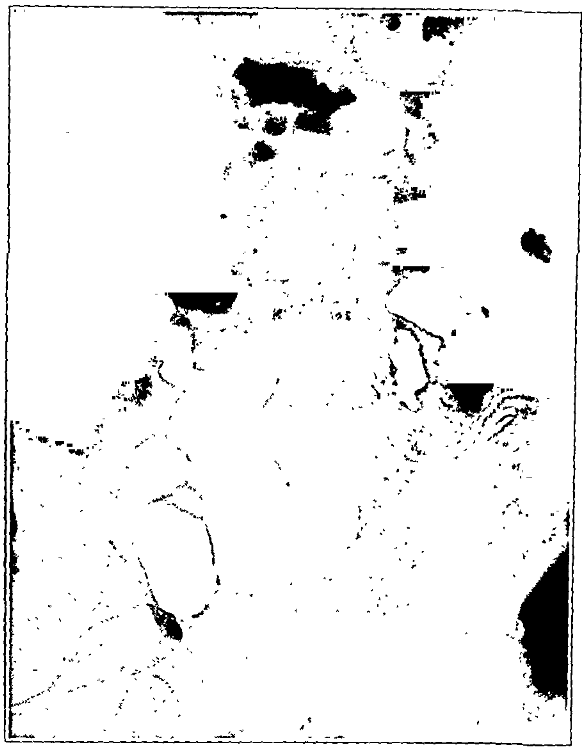

Fig. 2.—Same case as in figure 1. Film at six hours, shows barium-filled enteric canals of ascarids.

Following this, a series of sixty patients with stools positive for ascaris ova were studied roentgenologically. Three cases were picked up accidentally. At first, films were made every hour after ingestion of the barium cereal meal, up to the seventh hour. A few cases convinced us that films made at one, two and four hours would demonstrate any evidence of *Ascaris* which would be obtained by using a longer series. In the recent cases, we made films only at the three periods previously noted.

The sixty-three patients consisted of fifty-nine children and four adults. All had positive stools except in the three cases which were picked up accidentally. One of these was the case of the boy described before. A second case was found in the course of a routine gastro-intestinal examination of an adult. The third was a child on whom films were being made to demonstrate a normal gastro-intestinal tract. Of the fifty-seven children with stools positive for ova, fifty-four showed the very definite typical roentgen appearance described in the first case, and three were classified as negative. Of the three adults with positive stools, only one showed typical roentgen observations, two being negative.

The roentgen appearance is apparently perfectly typical. At first there are cylindric filling defects, usually in the jejunum, from 5 to 8 mm. in diameter and up to from 15 to 20 cm. in length. Films made some time after ingestion of the barium by the patient show stringlike shadows in the central portion of the filling defect, these strings being interpreted as the barium-filled enteric canal of the parasite (fig. 3). An interesting incidental observation has been that the parasites will not ingest the barium if the patient has eaten prior to drinking the contrast meal, and consequently the enteric canals will not be outlined. Our explanation for this is that if the patient has eaten food prior to the administration of barium, the enteric canal of the parasite will be filled and no barium will be ingested by the worm. On account of this, we have withheld food as though for a routine gastro-intestinal examination.

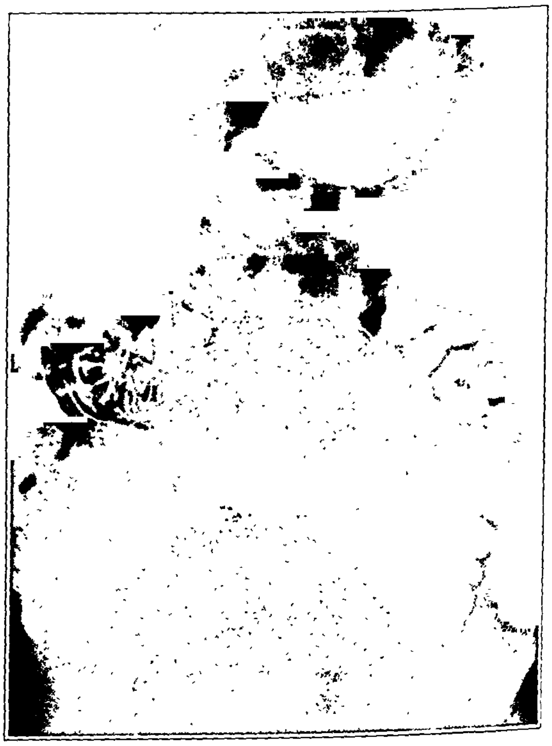

Fig. 3.—Typical appearance of ascarids in barium-filled jejunum, showing filling defects and barium-filled enteric canals of parasites.

COMMENT

In our series of cases only patients reported as having stools positive for ascaris ova were examined. In these the roentgen signs have been constant and have been present in a high percentage of infested children, only three of a series of fifty-nine failing to give the typical appearance. Our series of adults has been too small to give any idea as to the diagnostic accuracy. It is obvious, however, that the parasites can be more readily recognized in the relatively small jejunum of the child than in the larger bowel of the adult, since the size of the ascarid is constant. In our experimental work, we found two cases in which there were positive roentgen observations, with negative stool examinations. In our next study, patients will be taken from the clinic and have both stool and roentgen examinations made. In this manner the accuracy of the stool examination can be checked, in cases in which the stool has been reported negative for *Ascaris.* It is our belief that the recognition of the roentgen signs will be of the most value, not in *supplanting the stool examination* but in supplementing it in doubtful cases, and in demonstrating *Ascaris* in referred gastro-intestinal cases in which the referring physician has not made a stool examination. In certain rural districts, ascaris infestation is very common. In Cort's series, the stools of 2,152 individuals of Wise County, Va., were examined, showing 48.2 per cent positive for *Ascaris.* Other rural sections show almost as high a percentage. In general practice, routine microscopic stool examinations are far from routine; so in view of the frequent incidence of *Ascaris,* the roentgenologist should watch carefully for the easily demonstrable evidence on routine films made of the gastro-intestinal tract. It may prove advisable to make an additional film either one or two hours after ingestion of the barium, particularly in patients coming from rural sections.

Results of Observations

	Children		Adults		Totals	
Stools positive	57		3		60	
Roentgenogram positive		54		1		55
Roentgenogram negative		3		2		5
Stools negative	*2*		1		3	
Roentgenogram positive		2		1		3
Total cases		59		4		63

Much has been published in recent years regarding the clinical importance of ascaris infestation, and it is not in the province of this contribution to touch on this field. Suffice it to say that during the last few years an editorial on this subject has appeared about once every two years in THE JOURNAL.[14] It would appear that roentgenology supplies a valuable diagnostic aid which may clear up some hitherto doubtful clinical phenomena.

SUMMARY

Characteristic roentgen observations are present in a high percentage of children with intestinal ascariasis, as shown by a barium cereal meal.

These observations are: (1) soon after ingestion, a cylindric filling defect *in the jejunum;* (2) later a stringlike shadow, representing the barium-filled enteric canal of the parasite.

Roentgen evidence is occasionally definite in the absence of ova in the stool.

ABSTRACT OF DISCUSSION

DR. EUGENE P. PENDERGRASS, Philadelphia: In general, the roentgen diagnosis of ascariasis would seem superfluous, in view of the fact that microscopic examination is cheaper and more accurate in the presence of a few worms. Each mature female produces a large number of ova daily. On the other hand, there are cases in which the female specimens are absent and only males are present. In these one would have to depend largely on the roentgen examination to clinch the diagnosis. Ascariasis may simulate tuberculous peritonitis, duodenal ulcer, carcinoma of the intestinal tract, gallbladder disease, liver abscess, strangulations and many other conditions. Ascarids have caused asphyxia by obstructing the trachea. In children, the symptoms are usually restlessness, instability, grinding of the teeth, twitchings or convulsions. There is usually a marked anemia. It is obvious, therefore, that one should be familiar with the roentgen manifestations of this condition, because it may be possible to make the diagnosis when it is least suspected clinically. Dr. Archer found three cases accidentally in his series. The roentgen observations depend on two conditions: displacement of some of the opaque mediums by the worms and ingestion of some of the opaque mediums by the ascarids. Laurell, in his monograph on this subject, has observed that the contrast medium forms a thin layer about each worm, giving usually the appearance of two parallel lines, in some places less than 1 mm. wide. The female worm is from 7 to 12 inches in length and the male from 4 to 8 inches. They sometimes form slightly serpentine configurations within the lumen of the intestine. In the latter case, they often cross each other in acute angles and the roentgenogram will show parallel streaks and a sort of reticular delineation with oblong meshes. Small filling defects may be seen where there are cross-sections of worms. It is even possible to see the worms move. When several worms are together, some of the parallel lines will correspond to the triangular and prismatic spaces between several worms. The circular serpentine filling defects must be differentiated from the normal appearance cast by loops of small intestine caught in an axial plane on the roentgenograms. Dr. Archer's observation that the worms are less likely to cause filling defects in adults than in children because of the difference in the size of the lumen of the intestine is extremely important. This difficulty may be obviated, however, if one will bear in mind another of his observations; that is, to have the patient fast at least six hours before making the examination and to make roentgenograms two hours after giving the opaque medium.

DR. L. T. LE WALD, New York: Of course the question immediately comes into one's mind whether a tapeworm might be demonstrated in a similar manner. I suppose that the authors have been asked that before. The habitat of the tapeworm is such that it might also be coated and shown.

DR. VINCENT W. ARCHER, University, Va.: Several public health workers who came to the exhibit were greatly interested in the roentgen diagnosis of ascariasis because they said that the diagnosis of ova in the stools was quite difficult, contrary to general belief, because ascaris ova resembled vegetable fibers more closely than did the ova of any other parasite. Dr. Le Wald asked a question about tapeworm. I certainly have been asked that. Unfortunately, I have had only one case of *Taenia* infestation since I started doing this work, and with that patient I worked without success all one day trying to find roentgen evidence. However, in reading the foreign literature, I came across an article in Italian, in which the roentgenologic appearance of tapeworm was described.

Plagues and the Growth of Civilization.—Medical history is of far less importance as a disseminator of light on current problems of disease than as an interpreter of the ups and downs of human fortunes and as a softener of the bias which comes from stereotyped instruction when past history is viewed chiefly from the standpoint of martial activities or religious constraints and inhibitions. Disease, in the form of plagues and pestilences, appears to have been the biological factor most powerful in controlling the growth of civilization.—Oliver, W. W.: Stalkers of Pestilence, New York, Paul B. Hoeber, Inc., 1930.

UNUSUAL COMPLICATIONS OF PROSTATECTOMY

REVIEW OF TWO HUNDRED CASES *

WIRT B. DAKIN, M.D.
Attending Urologist, Methodist, Hollywood and Good Samaritan Hospitals
LOS ANGELES

My object in this paper is to report unusual complications that may occur, directly or indirectly, as the result of prostatectomy. These observations were recorded during the postoperative convalescence of 200 prostatectomized patients.

REVIEW OF THE LITERATURE

A review of the literature impresses one with the improvement of technic of this particular surgical procedure. In the light of present knowledge, reports of prostatectomy twenty-five or thirty years ago sometimes contain amusing incidents.

A general surgeon of that date states: "It is wise to inform a patient, who has been obliged to be catheterized before operation, that it may be necessary to continue this procedure after operation, but it is safe to promise him that catheterization will be much easier and comparatively painless." His experience at that date doubtless justified his extreme conservatism and warranted his avoiding to commit himself definitely.

The physician's statement is reminiscent of the footnote on all descriptive literature of bonds for sale. Following a glowing account of the wonderful merits of the bonds, which undoubtedly corresponds to the physician's reasons given the patient as to why he should be operated on, the bond literature always concludes with the words, "When, as and if issued and accepted by us, and while we do not guarantee the above statement," etc., etc.

ATTEMPTED REMOVAL OF INFLAMMATORY TISSUE

It is certain that the occasional average operator trying to take away too much prostate does not realize that what he assumes to be hypertrophy is really only inflammatory thickened tissue. In striving to enucleate this, he is attempting the impossible. The trauma, which this thickened tissue delivers to the vesical neck, is eliminated when enucleation is confined to the gland itself, which anatomically should be removed. Persistence in manipulating this inflammatory tissue prolongs the operation and encourages a stormy convalescence.

POSSIBLE CONTRAINDICATIONS

Diabetes should not be a contraindication to operation if the general preoperative care has not been neglected and the patient urologically is in good condition. The usual preparation was followed in my cases before the present treatment for diabetes was practiced, and these patients gave me no difficulty.

With the recent studies of myocarditis, much can be done to prevent an unfavorable outcome. A patient with myocarditis not too severe and which has existed for some time, if he can be carefully prepared before operation, should be able to withstand a prostatectomy.

The urologist should plan to give these patients plenty of time for their preoperative preparation and should be on the alert night and day for the first ten days following prostatectomy. The best nurses should be employed, warned of the danger signals, and instructed what to do at a moment's notice. If a nurse waits to locate the internist or operator, it may be too late.

It is best to watch carefully the pulse and blood pressure of every prostatectomy patient, whether he has myocarditis or not and no matter how good his preoperative condition. Observers differ as to how frequently these records should be made. I should say that the pulse should be taken every hour and the blood pressure every two hours during the first forty-eight hours. In some prostatic patients no mistake will be made in observing the pulse every half hour the first day.

COMPLICATIONS OCCURRING AFTER PROSTATECTOMY

Hunt reports the development of suppurative arthritis and empyema following too early passing of a catheter into the bladder after a prostatectomy. He attributes these complications to traumatization of the prostatic capsule, with infection disseminating into the blood stream, pyemia resulting.

Inability to void after operation is a rather embarrassing but fortunately infrequent occurrence. I find but two instances in my series of cases. Both were due to the closing of the vesical end of the urethra by scar tissue. The wounds refused to heal until the condition was corrected. In one case it was possible to open the urethra with the somewhat forcible passage of a urethral sound, leaving a retention catheter in situ until the wound was closed.

The second case necessitated enlarging the suprapubic wound and, under direct vision, excision of the scar tissue.

Although retention catheters aid in avoiding the closure of the urethra, they cause discomfort to most patients, with occasional rise of temperature from urethritis, and they repeatedly become occluded with débris. Unless they drain the bladder as intended, they are contraindicated.

Passage of sounds is also a poor procedure for many reasons. I never place a retention catheter or pass a sound the first week. If all is going well, the patient comfortable, and indications point to an early closure of the wound (i. e., passing of quantities of urine through the urethra), it is best to leave all instruments out of the urethra and keep the patient dry by reapplying dressings hourly. This is especially true when the nurse is inexperienced or the operator not thoroughly familiar with this kind of work.

In the foregoing complication, inability to void does not include cases in which not all of the prostate has been removed, or in which there is a large diverticulum, contracture of the vesical neck or spinal cord disease. These conditions would be easily recognized by a urologist.

Incontinence after operation is a comparatively infrequent condition. In the cases reviewed it seemed to be due to: (1) the removal of a very large prostate which was mostly intra-urethral and anterior to the internal sphincter; (2) too great or too continued pressure of either rubber bag or gauze packing; (3) debilitated and emaciated patients.

Peritonitis is an exceedingly uncommon condition, usually occurring when the surgeon has been obliged to go through scar tissue, the site of some former operation, or occurring at the time of the second stage in endeavoring to enlarge the operative field. An unusually high entrance into the bladder will always prevent tearing the peritoneal fold, because then any enlargement would necessarily be downward, else the

---

* Read before the Section on Urology at the Eighty-First Annual Session of the American Medical Association, Detroit, June 26, 1930.

lateral or inferior surfaces of the prostate could not be reached.

Pyelonephritis occurs more frequently than reports indicate. It is not known how often, because the lower urinary tract is in such urgent need of attention that the ureters are not catheterized. The etiology is usually from the prostate. The renal condition will improve or disappear after prostatectomy. Usually the patient should not be subjected to any more routine examination than is necessary. His general condition is poor; he is uncomfortable and needs immediate relief. Undoubtedly the increased muscular effort to empty the bladder and the obstruction to outflow cause ureteral reflux.

Relaxed musculature in these old persons, combined with their habit of spending much time in a recumbent position, tend to cause pyelonephritis. A persistence of the condition after a patient has entirely recovered from his prostatectomy would justify ureteral catheterization and all accompanying procedures.

Phlebitis is an uncommon complication also occurring in other fields of surgery and as the result of infection. I can report only one case. Phlebitis may persist from two to four weeks, causing considerable discomfort and necessitating the patient's remaining quiet with the leg elevated and with continued hot dressings.

The first or second week after the surface wound has healed the patient may present himself for the relief of slight pain and burning at the site of operation. Examination will reveal a localized tenderness and perhaps a small pustule. Incision of this will evacuate from 4 to 8 cc. of a semipurulent fluid mixed with serum. This condition is caused by a few shreds of necrotic tissue which did not separate and pass out of the wound before closure.

Too frequent application of stimulating drugs in an endeavor to hasten healing of the suprapubic wound may delay closure. I refer especially to too strong a solution of silver nitrate.

Hiccup is a rare occurrence if the patient's renal condition was satisfactory before operation. The etiology then is obscure. The treatment is very unsatisfactory. In some cases it is possible that the respiratory movement may cause the drainage tube or gauze pack in the wound to irritate the peritoneal fold. Removal of the gauze and tube and, in marked cases, a change of the patient's position, even getting him out of bed into a chair, are justified.

I was called in consultation in such a case recently. The urinary output was satisfactory, the general condition good, and preoperative laboratory reports were correct. I advised getting the patient out of bed and, with assistance, allowing him to stand on his feet and walk a few steps and stay up in a chair until he was tired. The next day I looked into the room as I passed and found the patient out. I inquired whether he was still alive, thinking of course of such complications as emboli; I was told he was out in the sunshine and entirely relieved of his hiccups.

Pulmonary embolus has wrecked the hope of many an operator who believed he was about to break the world's record on prostatic mortality. It is supposed to occur from getting the patient out of bed too early. As far as I can determine, it is reported about once in a hundred cases. If it is wished to shorten convalescence, hypostatic congestion should be avoided. Should ninety-nine patients be kept in bed to evade this rare complication?

The explanation of toxic psychosis is not easy. Even though all function tests are satisfactory, it seems to be of uremic origin. Its onset is sudden, it commonly persists not more than a day or two, and it disappears quickly. One writer records that a patient of his nearly choked a nurse to death before she was rescued. A patient of mine with toxic psychosis suddenly ceased being restless, began to notice what was going on in the room and said to the nurse, "I did not give you your check the other day. Give me my pen and all the bills." He signed his name as well as he ever did.

Postoperative hernia has not occurred in my series of cases when prostatic enlargement was the only complaint. One patient with a large diverticulum and a very large fat abdomen, necessitating an unusually long incision, developed a small ventral hernia. It has not troubled him sufficiently to be repaired. This was one of the most difficult diverticular cases I ever encountered. The procedure took so long that I hurried the abdominal closure.

Hernia never occurs in wounds carefully sutured. Patients who are very stout should be handled the same as in a hernioplasty.

Fistula should never occur in uncomplicated cases if the drainage tube is placed high, near the vault of the bladder, following the prostatectomy. This was pointed out by Squier and others more than twenty years ago. The complications I refer to which cause fistula are: vesical calculi that were overlooked or formed after the operation; contracture of the vesical neck; incomplete removal of the prostate; scar tissue formation at the vesical end of the urethra during the postoperative healing; diverticula; and, lastly, the thin walled abdomen of a debilitated patient. Following enucleation, it is well to pass a number 28 or 30 French sound through the urethra and palpate the internal orifice to see whether the vesical neck is well opened.

Few cases of vesical calculi are reported. They occur from overlooking small calculi at the time of operation, which later grow rapidly larger, encouraged by an unusually purulent alkaline urine and the patient's lowered resistance and predisposition to stone formation. This can be prevented by irrigating the bladder through the abdominal wound with 1,000 or 2,000 cc. of 0.5 per cent boric acid solution once or twice a day. During the second postoperative week this can be continued through the urethral catheter. Sodium acid phosphate and from 1,500 to 2,000 cc. of distilled water should be given by mouth each day.

Parotitis is seldom reported. It occurred twice in my cases and was accompanied by epididymitis. In one case the anesthetist thought it might be due to the use of an airway with resulting dilatation of Stenson's duct, allowing reflux of secretions into the parotid gland. In my second case a spinal anesthetic had been used. I now hesitate to venture an opinion as to the etiology of parotitis.

Pelvic cellulitis can be prevented by the technic of Dr. Edward Keyes or by allowing sufficient time to elapse after cystotomy before doing the second stage of the prostatectomy.

Uremia, hemorrhage, pneumonia, surgical shock and acute cardiac dilatation are frequent complications of which much has been written. They are more or less preventable and should not be included in this paper.

Rectovesical fistula, paralytic ileus, angina pectoris and erysipelas have been reported. I have encountered none of them.

Because autopsies cannot always be obtained, it is not possible always to know the real complication causing death.

REPORT, FROM AUTHOR'S CHARTS, OF INFREQUENT COMPLICATIONS

Case 1.—*Expulsion of portion of prostate through the urethra.* On the ninth postoperative day a patient complained of a frequent desire to urinate accompanied by very severe pain. Previously, nearly all the urine had been voided through the urethra, and the wound was almost healed. Unable to determine the cause of this unexpected state of affairs, I gave him a hypodermic from which he received practically no relief. After about two hours of urinary effort, he expelled a lobe of the prostate through the urethra. It was the size of a small cherry.

Case 2.—*Herpes zoster.* In the second postoperative week this patient complained of intense itching and burning of the skin on the left lower side of the abdomen and extending well down on the thigh. This greatly added to his discomfort and necessitated frequent doses of morphine and phenobarbital. He was entirely well from his prostatectomy before the skin condition disappeared. This particular case is of interest because such an insignificant disease as herpes zoster caused so much disturbance while a major operation gave no trouble.

Case 3—*Diaphragmatic hernia.* The fourth day after a prostatectomy the patient suddenly developed severe dyspnea, syncope, cyanosis, irregular pulse, marked pallor, hiccup, severe pain in the chest and a fear of impending death. He was able to breathe only when in an upright position. An internist, after a rapid examination, made a diagnosis of diaphragmatic hernia. Roentgen examination confirmed this. The patient died two hours later. This patient, although 79 years old, also had gonorrhea.

Case 4.—*Unusual postoperative hemorrhage.* During the night a nurse, as she passed through the ward, heard a patient complaining of pain. On investigation, she found that the patient had just pulled a small-sized Pilcher bag out through the urethra. He died that night from hemorrhage and shock.

Case 5.—*Hyperpyrexia of 108 F. without death.* This patient suddenly developed chills and fever during the third postoperative week. His temperature gradually rose to 104, 105, 106, then receded to 105, and again rose to 106, 107 and 108. This occurred on three different occasions within a week. The patient was delirious, of course, and considerable assistance was necessary to restrain him. Previously he had been voiding normally, and his wound was nearly healed. The thermometer was checked and found to be correct. The patient recovered and still has this thermometer as a souvenir. This occurred nine years ago. The patient is now in good health and lives in Pasadena. Such high temperatures occur in typhoid, meningitis, septic abortion, Mediterranean fever and heat stroke. He had none of these diseases. What was the cause of the rise of temperature?

756 South Broadway.

ABSTRACT OF DISCUSSION

Dr. Arthur L. Chute, Boston: I agree with most of the points Dr. Dakin raised. With me the mental upsets of these patients have been more troublesome than he has found them. I have a man under observation now who has been psychotic for two or three weeks. The last report I had was that he had scratched his male nurse's face with his toe nails the night before. I am glad that these cases are milder on the Pacific coast. As to hiccup, I have had that persist for several days, if I remember rightly, even up to a week or a little longer. I find that filling the patient up with salt solution usually relieves it. I know of nothing to do for the severe cases of embolism, whether they are pulmonary or coronary; the severe ones are promptly fatal and the mild ones, especially of the lungs, are recovered from. I fear that my incidence of embolism is greater than 1 per cent. I believe that paralytic ileus is just a manifestation of the toxic condition so often seen in prostatic cases. Within the year there has come to my notice the third enterostomy for this toxic distention. It did no more good than was the case with the other two, the first of which I did myself many years ago. This should never be considered. If these patients are to get well they will get well under the use of salt solution under the skin: often it must be given in enormous amounts, from 4,000 to 6,000 cc. a day, for several days. If the patient's heart muscle is poor, I know of nothing that will remedy this condition. The use of repeated enemas and of hot applications to the abdomen in conjunction with the salt solution are of great help in the successful treatment of those cases.

Dr. J. H. Morrissey, New York: Dr. Dakin did not mention one complication, dermatitis exfoliativa. I saw it in a patient who was operated on for prostatic hypertrophy, went home in due time, and several days later developed a mild psychosis for which he was brought back to the hospital. At the time he had a rash on his head and neck which resembled scarlet fever. Several skin consultants were invited to see the case and made the diagnosis, stating that it was due to a probable collection of pus somewhere. The old wound and bladder region were thoroughly explored without success and finally the rash involved the entire body with its characteristic reactions. Gradually the urea nitrogen mounted from 85 mg. per hundred cubic centimeters to 128 and his white count ran around 39,000. Owing to the absolute cessation of skin excretion his condition became worse and when his total nonprotein nitrogen was 275 he died. During the three weeks in which he lived he had an intravenous saline injection of 2,000 cc. daily. This shows the value of the skin as a means of excretion and when such an area is shut off, that a much greater strain is put on kidneys that are already damaged. Several older urologists who saw the case told me they had seen three or four cases in the past twenty years and that they were invariably fatal. The condition is a true infection of the derma, which is thickened and swollen and exfoliates to such a degree that the scales could be brushed out of the bed at night. It was very disappointing to have this patient, who had gone through a severe operative procedure as the result of having catheterized himself for two years with infection, die of a skin complication. I think it was due to the fact that he was too debilitated when the second stage operation was performed, as I should have waited a week or two longer.

Dr. William E. Lower, Cleveland: There is one complication which might be a factor in the causation of prostatic hypertrophy, and that is chronic inflammation, which is nearly always found in these cases. Recently in taking cultures of the removed prostates I have found that 70 per cent yield growths usually showing the colon bacillus. As these glands are wet, there must be an excessive secretion in them, and this excess secretion may be stimulated by the chronic inflammatory condition. If a chronic inflammation is considered as a possible factor in the production of hypertrophy, this may be counteracted in some way. These infections, I believe, are usually metastatic infections, often from the respiratory tract, as after influenza. It would be instructive, I think, if cultures of removed prostates were taken as a routine and the resultant growths reported.

Thinking Revolutionized by Science.—No one, today, doubts that science holds a place of the first rank in building up and in maintaining our highly mechanized civilization. Few would venture to question the dominance of science in its relation to industry, or the benefits that it has conferred on humanity through sanitation and medicine. In the field of higher education its opponents have constantly lost ground, until it may now be said that science, both in the faith of the many and in the curricula of our numerous educational institutions, holds the commanding position that was formerly given to the humanistic studies. The former antagonism between science and the humanities is rapidly being dispelled and a new order of educational procedure is coming into being. The conflict between science and religion has, in the more enlightened communities, passed into the realm of history, and at present their interests are seen to be in cooperation rather than opposition. In every field, human thinking has been revolutionized by the knowledge gained through science and the scientific method.—Saidla, L. E., and Gibbs, W. E.: Science and the Scientific Mind, New York, McGraw-Hill Book Company, Inc., 1930.

MIGRAINE

RESULTS OF TREATMENT BY KETOGENIC DIET IN FIFTY CASES [*]

CLIFFORD J. BARBORKA, M.D.
ROCHESTER, MINN.

Early in my experience with the ketogenic diet,[1] it was tried in cases of migraine. Since then Lennox and Cobb,[2] in their monograph on epilepsy, have stated that it would be of interest to know whether the induction of acidosis is of benefit in cases of migraine. Since the original report from the Mayo Clinic,[3] Schnabel [4] has reported his experience with a ketogenic diet in cases of migraine.

Some of the recent etiologic theories and therapeutic suggestions are of interest in considering the justification of a ketogenic regimen in cases of migraine. R. and S. Weissmann-Netter [5] found apparent changes in the acid-base balance: the hydrogen ion concentration and alkali reserve are normal in the periods of freedom from attacks but a tendency to alkalosis develops forty-eight hours prior to an attack. The recent method of studying acid-base equilibrium by hyperpnea or overventilation of the lungs, which induces alkalosis, was utilized by Muck,[6] who by this method produced hemicranial attacks in cases in which the patients were subject to migraine. Most patients, because of the nausea and vomiting with the attacks, voluntarily fast until relieved, thereby producing fasting ketosis. Bigland [7] called attention to the use of large doses of calcium lactate in an effort to lessen the irritability of the nerves.

TABLE 1.—*Observations on Patients Whose Conditions Had Been Controlled*

Case	Age	Sex*	Attacks Before Treatment	Disease, Years	On Diet, Months	Ketosis	Comment
1	28	♀	About once a week, lasting two to three days	13	23	Always present	Attacks disappeared after two months
2	26	♀	Twice a week, lasting about two days......	19	7	Always present	Headaches frequent first six weeks on diet; none since
3	29	♀	Two to three time a week, lasting twelve to eighteen hours	19	20	Periodic	Controlled after first two months
4	37	♀	Once a week, lasting twelve to thirty-six hours	27	9	Always present	First month on diet less severe headache every week; then entirely free since
5	33	♀	Two to three a month, lasting two to three days	8	23	Periodic	After first two months free from attacks
6	44	♀	At least two a month.................... ...	32	16	Periodic	Attacks disappeared after two months
7	21	♀	One to two a week, lasting several hours...	4	14	Always present	After two months some relief; after three months arrested
8	52	♀	One to two a week, lasting one to two days, *menopause at thirty-eight; no alteration in attacks*	25	16	Always present	After two months no headaches
9	23	♀	Cyclic vomiting beginning at age of two years; migraine at 14; attacks about every five to six weeks	21	15	Always present	Controlled since ketosis developed
10	31	..	Once and sometimes twice a week..........	21	18	Almost always present	No headaches after first three weeks
11	30	♀	Three to six weeks..................	17	13	Always present	Attacks controlled since being on diet
12	27	♀	One to three a week lasting about twelve hours	15	9	Periodic	Attacks controlled since fourth week on diet
13	54	♂	Cephalic migraine thirty-eight years; abdominal migraine last two years	38	36	Present one year, periodic since	Both abdominal and cephalic migraine disappeared after six weeks
14	25	♀	Every two to four weeks..................	8	9	Almost always present	One attack in first three months; none since

* In the tables, ♂ indicates male; ♀, female.

The suggestion that migraine is sometimes a phenomenon of protein sensitization is not new. Pagniez [8] and his associates assumed that migraine is an anaphylactic manifestation. Miller and Raulston [9] continued the work in this country. Vaughan,[10] Rowe,[11] and many others have considered migraine from the standpoint of an allergic manifestation. Curtis-Brown [12] proposed the theory of inherited impaired metabolism with intolerance of nitrogenous foods, a protein-poison theory. They advocated various forms of treatment from the use of peptone to the restriction of certain proteins.

Chiray,[13] Duval,[14] Diamond,[15] Hetinyi,[16] McClure and Huntsinger,[17] and others have approached the problem from the standpoint of dysfunction of the liver and duodenum. They have called attention to biliary stasis as an etiologic factor. The French literature has emphasized duodenal migraine; in it evidence is presented of disturbed hepatic function as estimated by the van den Bergh reaction and retention of bilirubin. Many patients with so-called bilious headaches have been improved by intraduodenal administration of magnesium sulphate to stimulate the flow of bile. A distinct increase in the size of the liver may occur during an attack; the liver may be definitely tender and palpable to a degree not found between the attacks. I have found in some cases that a definite increase in the bile pigment of the plasma occurs coincidently with the headaches.

Brown[18] emphasized the part diet plays in the etiology and treatment of migraine. It does seem that the character of the diet plays some part in the explosive phenomena of an attack of migraine if only as a secondary or contributing factor. It is recognized that nervous strain, the vasomotor instability associated at the time of the menstrual period, emotional excitement, fatigue and various psychic phenomena unquestionably are contributory factors, but in many cases it is quite impossible, either physically or psychically, to explain the migraine on such a basis alone, and other factors making the patient susceptible must be found.

Many patients volunteer the information that excessive use of carbohydrates results in a headache, even the taking of a cup of chocolate or a piece of candy. There are also patients who feel that protein is the food that precipitates the attack. In the largest group, the excessive intake of carbohydrates, or an amount excessive for the individual's tolerance, precipitates an attack. Hare,[19] Brown and Minot [20] have emphasized the rôle of a diet low in carbohydrate in the treatment of migraine.

The ketogenic diet, of course, is a diet low in carbohydrate, but it offers more than restriction of carbohydrates. If alkalosis induces migraine, the ketogenic diet which produces ketosis, with an accompanying decrease in the irritability of the nerves, might be an additional inhibiting factor. From the standpoint of an allergic manifestation, because the content of protein in the diet is low it is possible that there is a chanc withdrawal of the specific protein element. Boyden[2 has shown that a diet high in fat promotes biliar drainage, and it has been demonstrated also tha duodenal motility occurs after ingestion of fat. Therefore, benefit could be expected in the cases due t dysfunction of the liver and duodenum.

With these facts in mind, it can be seen that the us of the ketogenic diet is not without logic, as potentiall it could cover, in a therapeutic manner, all of the foregoing suggestions at the same time.

ADMINISTRATION OF THE DIET

The ketogenic diet denotes a diet having high fat an very low carbohydrate constituents in definite but varie proportions which result in the excretion of keton bodies. This form of diet influences the acid-base balance and produces certain physicochemical changes in the tissues of the body which deserve a great deal of further investigation and study. This form of treatment is to be applied quantitatively in selected cases as an accurately controlled and supervised experiment rather than to be accepted as a proved specific remedy for migraine.

My purpose in making these observations was to determine whether or not the results of the treatment of severe typical migraine by the ketogenic diet would justify the necessary effort and sacrifice on the part of the patient. It is realized that the ketogenic diet cannot be used as a routine because of certain difficulties, which have been reported.[1]

The cases that were selected for this study included only those in which there had been frequent attacks of typical migraine and those in which attacks were unusually severe; it is recognized that many headaches

Table 2.—*Observations on Patients Benefited*

Case	Age	Sex	Attacks Before Treatment	Disease, Years	On Diet, Months	Ketosis	Comment
15	33	♀	Two to three a week, lasting six to twenty-four hours	11	10	Periodic	Attacks gradually decreased to about one a month
16	23	♀	One to two a week, lasting six to twenty-four hours	10	12	Periodic	Attacks about once in two months since on diet
17	16	♀	Two a week; twelve to twenty-four hours..	4	11	Periodic	Occasional slight headache of short duration
18	21	♀	Two a week.......	15	6	Periodic	Headaches gradually lessening in frequency and severity
19	29	♀	One a week, lasting from twenty-four to *forty-eight hours*	8	24	Periodic	Headaches controlled on diet but with breaks in diet *recurring headaches*
20	23	♀	One or two a week; shortest attack one hour; longest attack three days	16	8	Periodic	Headaches gradually decreased in frequency and severity; occur only with breaks in diet
21	40	♀	Two a month at first, lasting one to two days; last five years one to two a week	10	10	Periodic	Only *four severe attacks* since on diet; menopause not entered
22	24	♀	One to two a week.........................	8	22	Periodic	Attacks one in two months; gradually lessening in frequency and severity
23	29	♀	One every three or four weeks; last few years, two a month	14	12	Periodic	Great lessening in frequency and severity of attacks
24	39	♀	Two or three a week...	27	11	Periodic	Only six attacks, not *severe, since* on diet
25	30	♀	Two to four a week, lasting about six to twelve hours	11	15	Always present	Attacks reduced to about one a month
26	27	♀	Two to three a week.......	12	18	Periodic	One mild attack every few weeks
27	33	♀	Two or more a week, lasting twelve to twenty-four hours	29	15	Periodic	Attacks less frequent and less severe
28	16	♀	Once a week, lasting two days...............	10	12	Always present	Attacks less frequent and less severe, coming about once in six weeks
29	27	..	Severe migraine twice a week; the last two *years, abdominal migraine associated*	8	16	Periodic	One or two slight headaches a month
30	42	♀	Three or four a week.......................	36	14	Periodic	Headaches very much improved; attacks once or twice a month; menopause not entered
31	25	♀	One to three a week........................	5	8	Periodic	Attacks once a month but just as severe
32	35	♀	At least one every ten days; sometimes every other day	27	6	Periodic	Two attacks first three months on diet; none in next three months; patient then broke diet
33	66	♀	Every week or two...........................	54	6	Periodic	Attacks less frequent and less severe
34	31	♀	Once a week...................	18	7	Periodic	Four attacks in seven months
35	39	♀	Three days to three weeks, lasting three to ten days	10	8	Periodic	One attack a month of shorter duration and less severe
36	40	♀	Every ten days.............................	28	10	Periodic	Four attacks since on diet; less severe and about half as long
37	32	♀	Once a week................................	20	17	Periodic	Attacks occurring only at menstrual period; none for last four months
38	28	♀	Every eight to twelve days..	16	6	Periodic	Headaches only once a month since on diet
39	49	♀	Twice a week.............	37	8	Periodic	Headaches less severe; about one every other month

accompanying neurosis and psychosis are often termed migraine or rather atypical migraine, and this group was purposely avoided for this particular study. Further selection was made of only those cases in which the patients were willing and able to spend adequate time to learn the manner of maintaining and adjusting the ketogenic diet so as to be able to carry on the regimen at home for at least a trial period of six months. Women rather than men were selected for observation in this first trial series as it seemed certain that they would follow the regimen more accurately.

Fatigue, and the emotional and the psychoneurotic state of patients leading hurried, complex lives with a great deal of mental stress and strain, as well as lack of exercise and outdoor life, may be factors precipitating or aggravating migraine; any change of environment may relieve such patients temporarily. An attempt was not made to alter the lives or change the mode of living of the patients in my series. The only requirement insisted on was the effort and the willingness of the patients to follow and maintain the ketogenic diet to the best of their ability for the six months' trial.

TABLE 3.—*Observations in Failures*

Case	Age	Sex	Attacks Before Treatment	Disease, Years	On Diet, Months	Ketosis	Comment
40	30	♀	Two to four a week..........................	14	6	Never present	Headaches less severe but just as frequent
41	30	.:.	Two to four weeks; very severe...........	18	4	Always present	No benefit in four months; diet stopped
42	40	♀	Every ten days..............................	14	3	Never present	No change after three months; diet stopped
43	32	♀	One every two weeks........................	12	4	Always present	No change after four months; diet stopped
44	44	♂	Cyclic vomiting of childhood; attacks every week or two	40	3	Never present	No change after three months; diet stopped
45	43	♀	Every two weeks, lasting half a day to two days; not in menopause	35	4	Occasionally present	Attacks every four weeks; just as severe
46	43	♀	Two a week, lasting two or three days at a time	23	6	Periodic	Attacks about once in ten days
47	37	♀	Eight to ten days..........................	5	6	Never present	Practically no change in attacks
48	33	♀	Every two weeks............................	6	5	Never present	Attacks not influenced by diet
49	33	♀	Every three weeks, lasting two to five days	20	6	Periodic	Attacks practically the same
50	35	..	Ten to twelve days, lasting twenty-four to thirty-six hours	20	5	Periodic	Headaches as regular and last as long as formerly but not so severe

Most of the patients had resorted to all types of medical treatment, and sometimes to surgical treatment, without benefit. They were desperate and were willing to attempt any procedure, regardless of the effort involved. Since treatment of migraine by the ketogenic diet must be continued throughout an indefinite period of time, it is extremely important to guard against any evil effects that might result from lack of protective food if the diet should prove inadequate. Therefore adequate calories, protein, salts and vitamins must be provided.

An interpretation of statistics and results, especially concerning a condition such as migraine, cannot be made that is not subject to error. Every one recognizes that there are many factors that may enter into the aggravation of, or the temporary cessation of, attacks. Nevertheless, I feel that the benefits thus far derived have been sufficiently encouraging to justify the further use of the ketogenic diet in the treatment of severe typical migraine.

RESULTS

The patients in this series have been on the ketogenic diet from three to thirty-six months. For purposes of study the cases have been tabulated in three groups: (1) those in which the attacks of migraine have been controlled by the ketogenic diet; (2) those in which there has been definite improvement by lessening of the frequency or severity of the attacks, and (3) those in which the treatment failed. The age of the patients varied from 16 to 66 years; the period over which attacks of migraine had occurred varied from four to fifty-four years prior to the time of treatment.

Fourteen of the fifty patients controlled the migraine by the use of the ketogenic diet (table 1). The cessation of the headaches varied from the time ketosis developed to as long as three months. Most of the patients in this group maintained constant ketosis; a few experienced temporary disappearance of ketosis for a few days. The patients in this group have been on the diet from seven to thirty-six months.

Twenty-five patients (table 2) have been definitely benefited; the attacks of migraine are less common and less severe. Only two patients (cases 25 and 28) maintained ketosis; the remainder were periodically in ketosis. The migraine of some of the patients in this group was controlled for the time they were in ketosis, and when they broke the diet, recurrence of the migraine followed.

Eleven patients (table 3) did not derive any benefit from the procedure. These patients made an effort to follow the diet from three to six months. Two patients (cases 41 and 43) maintained ketosis constantly, but without any influence on the attacks of migraine. Four patients (cases 45, 46, 49 and 50) were in ketosis periodically, and the remaining patients did not reach the state of ketosis.

It should be noted (table 4) that in the fourteen cases in which the attacks were controlled, diacetic acid, tested for daily, was always present in nine cases, and was present intermittently in five. In the twenty-five cases in which the condition was improved, ketosis was maintained in only two, and in twenty-three it was periodic; the diet apparently produced a state of threshold ketosis. Of the eleven patients who were not benefited, only two maintained the diet accurately and were in a state of ketosis, and this was for four months only; they became discouraged because of not receiving benefit and discontinued the diet. Four of the eleven patients were periodically in ketosis and five did not reach this state at any time.

SUMMARY

Fifty patients who were suffering from severe typical migraine were treated with a ketogenic diet. The attacks of fourteen patients were controlled. Twenty-five patients were definitely improved. Thus, thirty-nine patients were benefited by the diet. Eleven patients were not benefited and the treatment was considered a failure, although a number of the patients were not maintained in a state of ketosis.

BACTEREMIA AND ACUTE THROAT INFECTIONS [*]

HOWARD C. BALLENGER, M.D.
CHICAGO
MITCHELL I. RUBIN, M.D.
BALTIMORE
AND
MARIE WERNER, B.S.
CHICAGO

In an attempt to determine whether a bacteremia can be demonstrated as an occasional or a frequent accompaniment of an acute or a subacute infection of the upper respiratory tract, series of blood cultures were taken at various times in children at the Children's Memorial Hospital, Chicago. In connection with these blood cultures, additional cultures were taken of the throat, nose and some of the complications, when present.

We were unfortunate in not finding many cases of the typical type of throat infections in the very early stage that we desired, that is, while the throat and nose were acutely inflamed with a temperature of 102 F. or over and before any complications such as mastoiditis, pneumonia or appendicitis had occurred. However, we found a great number of subacute throat infections in some of which secondary manifestations had occurred with the apparent etiologic factor in the throat infection. It is with these types of cases that this report deals largely.

BACTERIOLOGIC TECHNIC

From 5 to 10 cc. of blood was drawn from the external jugular or arm veins and placed directly in flasks containing 50 cc. of nutrient broth. The flasks of broth were heated to approximately 37 C. before being used and were placed in the incubator immediately after the blood was added. The cultures were observed daily for growth over a period of two weeks. Growth was determined by making a Gram stain of a loopful of culture. When the broth above the blood remained clear, the culture was not opened but was shaken and replaced in the incubator. The cultures were always streaked on blood agar and examined for growth before being discarded. Later, instead of being placed directly into the mediums, the blood was drawn into sterile flasks containing glass beads and defibrinated blood. Approximately 1 cc. of the defibrinated blood was placed in each of two tubes of 0.1 per cent dextrose brain broth. Cultures of the remaining blood were made in 50 cc. of broth as before. In a few cases, aerobic and anaerobic plate cultures were made.

Nose and throat cultures were taken on blood agar, with a few exceptions when broth was used, and the predominating organism was noted.

The ages varied from 1½ years to 14 years, with an average of about 5¼ years.

Almost all the children had an elevation of temperature at the time the cultures were taken with an average of about 102.3 F.

The white blood cell counts were taken in twenty-nine cases. They varied from 13,700 to 39,000, with an average of about 23,000.

RESULTS

Ninety-three throat cultures were taken in which the green cocci were found to be the predominating organism in sixty-four instances (about 69 per cent). *Streptococcus hemolyticus* was obtained in twenty-one cultures (about 23 per cent); *Staphylococcus albus* in six instances (about 7 per cent). *Staphylococcus hemolyticus* was isolated in two cases. The Klebs-Loeffler bacillus was incidentally found in two throats.

Eighty-seven cultures were taken from the nose. The predominating organism found in forty-four instances (about 50 per cent) was *Staphylococcus albus*. This is in marked contrast to the throat cultures, in which this organism occurred in only 6 per cent of the cultures taken. The green cocci were next in order of frequency, occurring in thirty-one instances (about 36 per cent). *Streptococcus hemolyticus* was found in the nose in ten cultures (about 12 per cent). *Staphylococcus aureus* and *Staphylococcus hemolyticus* were recovered once each.

The throat and nose cultures were taken together in twenty-nine instances. A streptococcus and a staphylococcus were found in about two thirds of the cultures. The green coccus was isolated in eight instances.

Cultures of the mastoids were taken at operation in five cases. *Streptococcus hemolyticus* was obtained three times, a green coccus and a pneumococcus once each.

Cultures taken from the appendix at operation in three cases revealed *Streptococcus hemolyticus* in two instances and a green coccus in one case.

Streptococcus hemolyticus was recovered from a profuse ear discharge in the one case in which a culture was taken.

Cultures of the spinal fluid in the two cases taken were negative.

BLOOD CULTURES

One hundred and thirty-one blood cultures were taken in sixty-three cases. In four children a positive culture of the blood was obtained. *Streptococcus hemolyticus* was found in two cases and a green coccus and a pneumococcus in one instance each.

The case of pneumococcic infection of the blood stream (case 39) is of interest as the organism was recovered from the blood before a clinical diagnosis of pneumonia was made. The first cultures taken from the throat and nose showed *Streptococcus hemolyticus*. The later culture from the throat and nose revealed a green coccus.

The child in whom a green coccus was recovered from the blood stream (case 1) died from a heart and cerebral embolism. The green cocci were also obtained from the throat. *Staphylococcus albus* was the predominating organism from the nose.

The first case of a hemolytic streptococcus recovered from the blood stream (case 7) was in a child with an acute suppurative otitis media of about ten days' duration, at which time a beginning pneumonia of the left lower base occurred. The streptococcus was obtained from the blood stream on two successive days. The same organism was also found in the ear discharge. Green cocci were isolated from the throat, which was not acutely inflamed at the time the throat cultures were taken. *Staphylococcus albus* was the predominating organism in the nose.

[*] This article is abbreviated in The Journal by the omission of the tabulated report of cases. The complete article appears in the Transactions of the Section and in the authors' reprints.

The second case in which a hemolytic streptococcus was found in the blood stream (case 63) is a striking example of a bacteremia from an acute throat infection in which the diagnosis is substantiated by an autopsy:[1]

Richard K., aged 3½ years, was first seen April 24, at 1 p. m. by Dr. Louis W. Sauer because of repeated vomiting and two liquid evacuations. He had been indoors several days with a slight head cold but was taken on a rather long automobile ride the day before (April 23). That evening he ate a hearty supper, was playful, slept most of the night, and ate his breakfast the next morning as usual. About 10 a. m. he vomited for the first time and retained nothing after that. The temperature was 101 F.; the respirations were 28; the pulse was good. He was not in pain, could sit up, stand up and lie down. Examination made by Dr. Sauer at 1 p. m. was negative except for a slight laryngitis and marked pharyngitis. The lungs, heart, abdomen, reflexes, eyes, nose and ears were normal. The child appeared to have an upper respiratory infection involving mainly the larynx and pharynx.

That evening, about 8 p. m. he suddenly became much worse with unconsciousness, extremely pale color, labored respirations of about 50 and a slow, weak but regular pulse. The temperature was 103 F. Numerous coarse and fine râles were found over the entire chest; the reflexes were reduced; the pupils were large and responded slowly to light. Vomiting had occurred all the evening with the last vomitus containing brown blood. At this time, he was given 10 minims (0.6 cc.) of epinephrine hydrochloride intramuscularly and then taken to the Evanston Hospital. On arrival, 150 cc. of dextrose Ringer's solution was given by hypodermoclysis. Within a few minutes he had a series of short convulsions with death at 1 p. m., about twelve hours after the onset of symptoms.

Since the child was exceptionally well developed, overweight, and had had chronic eczema during the first two years of life, a tentative diagnosis of status thymicolymphaticus with beginning capillary bronchitis was made by Dr. Sauer at this time.

Autopsy performed a few hours after death revealed acute pharyngitis, laryngitis, tracheitis and hypostatic congestion of both lungs. The thymus weighed 23 Gm. The lymph glands of the mesentery, Peyer's patches and solitary follicles were rather large. There was no sign of pressure by the thymus on the trachea, nor was there any local edema. The following day the throat culture and the plates of the heart's blood showed innumerable streptococci of the hemolytic type. This observation led to the diagnosis of acute streptococcic septicemia, following a streptococcic throat infection in a young child with lymphoid hyperplasia. Death was evidently due to the overwhelming flood of hemolytic streptococci in the blood stream with the probable portal of entry from the throat.

CONCLUSIONS

A bacteremia secondary to an acute or a subacute throat infection is not easily demonstrated by bacteriologic examination of the blood stream.

An occasional bacteremia can be shown to accompany an uncomplicated acute throat infection.

Streptococcus hemolyticus was found more frequently in the acutely inflamed throats and the green cocci in the subacutely injected throats.

In the various complications that may be due to an acute throat infection, *Streptococcus hemolyticus* was found in two thirds of the cases.

ABSTRACT OF DISCUSSION

Dr. Samuel Pearlman, Chicago: If routine blood cultures were made in all cases of acute upper respiratory infection, no doubt the number of positive observations would be a matter of surprise. Conversation with a number of competent bacteriologists leads me to believe that a rough figure of 5 per cent would approach the truth. However, and this is important, in most instances after the first two or three days the cultures would no longer be positive. Should they persist, no matter what the clinical picture at the time, one has the right to suspect that grave mischief is brewing and a careful search should be made for evidences of early endocarditis, early pneumonia, arthritis or peritonitis. The serious sepsis sometimes following instances of angina would no doubt be diagnosed earlier and proper treatment instituted sooner if routine blood cultures were taken in every case of sore throat that was not doing well. The authors' work calls attention again to an extremely valuable laboratory aid which many do not avail themselves of often enough.

Dr. Howard C. Ballenger, Chicago: A positive blood culture would perhaps be nearer of attainment if blood from the internal jugular vein were taken, but that seems rather formidable and we did not do it.

TONSILLECTOMY IN THE TREATMENT OF ACUTE CERVICAL ADENITIS IN CHILDREN *

HARRY L. BAUM, M.D.
DENVER

It may be safely stated that one of the most common sequelae of acute tonsillitis and tonsillopharyngitis in children is anterior cervical adenitis. So true is this statement that it might even be enlarged on to the extent of saying that almost 100 per cent of acute tonsillopharyngeal infections have an associated lymphadenitis of the anterior cervical glands. This high percentage would, of course, include cases of such mildness as to exclude them from the scope of the present paper, which is based on a series of forty cases of sufficient severity to justify tonsillectomy as a means of controlling the infection in the glands while that infection was still at its height.

I shall go into considerable detail in describing the usual onset and course of cases of acute cervical adenitis in order that the reader may fully understand the exact type of case in which I advocate the removal of tonsils for a cure. Tonsillectomy for chronic cervical adenitis has long been accepted and practiced,[1] but a fairly painstaking review of the literature does not reveal any instance of definite recommendation of tonsillectomy as a treatment in cases of acute cervical adenitis during the most active stage of the disease. In fact, one author[2] definitely states that early removal of the tonsils predisposes to breakdown of the glands, while another[3] states just as definitely that the operation should not be performed until the acute stage of the disease has passed on account of the danger of septicemia. Many others also recommend waiting for the subsidence of the acute symptoms. Tonsillectomy and adenoidectomy during the acute stage has therefore been practiced only here and there sporadically by surgeons who doubtless felt that they were treading on dangerous ground and who may have done the operation against the advice of others. This is the attitude which I desire to influence and, if possible, to change.

[3] Wagner (footnote 1).

The forty cases which are referred to here have been very carefully selected and were all private patients, the average age for the series being 3.6 years. Only those which conform strictly to every requirement of the paper have been included, which means that all showed acute enlargement of the anterior cervical glands following a tonsillopharyngeal infection, with soreness and tenderness of the glands, stiffness of the neck, general prostration of varying degree, high and usually irregular fever, an increase in leukocytes and in percentage of polymorphonuclear neutrophils, and a decrease in hemoglobin. In addition, the antecedent acute throat infection may or may not have been observed personally by the writer in each case but, if not, it was under the observation of a competent pediatrician during at least a part of its course in almost every instance. In the few exceptions to this rule the history has been carefully checked with the parents to verify the fact that an acute upper respiratory infection invariably preceded the development of the adenitis.

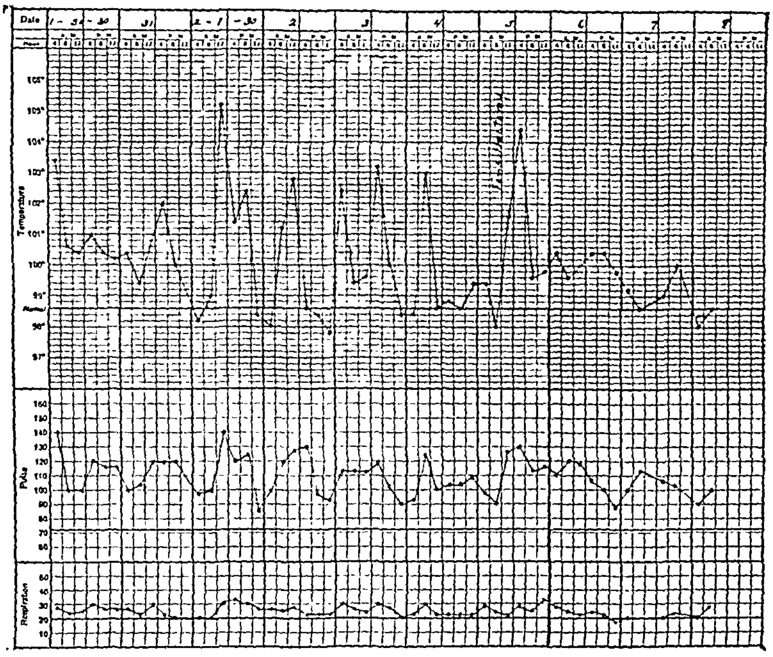

Chart 1.—Temperature in a typical case of acute cervical adenitis. (Note irregular type of temperature and rapid improvement following opration.)

CLINICAL PICTURE

The typical picture of the onset of these cases is that of a primary upper respiratory tract infection, occurring usually during a seasonal epidemic, and coming on acutely. This most frequently manifests itself as a tonsillopharyngitis, sometimes as a simple tonsillitis, and occasionally with apparently little or no tonsillar involvement, but only a pharyngitis. It usually also involves the nasal chambers in the form of an acute rhinitis, and if roentgenograms of the sinuses are taken the congestion in the antral mucosa will almost invariably result in an appearance of increased density, which will also be true of the ethmoids if those cells are sufficiently pneumatized for accurate diagnosis by that means. It follows without saying that the adenoid mass participates in the acute inflammation, which involves in greater or less degree practically the entire mucous membrane of the upper respiratory tract at some period of the disease. Later, of course, as in all acute upper respiratory infections, the inflammation may travel downward to involve the larynx and tracheobronchial tree, but that is usually of secondary importance and may frequently be so mild as to show no symptoms whatever. It seems almost invariably the case that when the infection expends its force violently in the upper respiratory mucous membranes and in the glands it does not develop into a severe type of involvement in the lower respiratory tract.

This acute upper respiratory infection usually begins to subside in from three to four days, so that at the end of a week the temperature is normal, or nearly so, the throat is no longer acutely inflamed, and any exudate which may have been present on the tonsils, in their crypts or studding the lymphoid follicles of the pharyngeal mucous membrane proper has almost entirely disappeared.

It is at this juncture that the adenitis usually makes its appearance, although it may have had its beginnings before that time and without an appreciable intermission between its onset and the antecedent infection, but with a gradual passing over from the one into the other. The temperature may have been normal for from one to three days or even much longer and the patient may apparently be on the road to recovery when the glands develop their swelling, the temperature rises and the patient again becomes acutely ill. The throat is now no longer sore, although the tonsils may still be slightly swollen and may retain in their crypts a thin fibrinous exudate but without the acute inflammation which goes with a violent tonsillitis. The pharyngeal mucosa may still be slightly congested and the same may be true of the nasal membranes. Later in the course of the disease, and because of the anemia, both the tonsillar and pharyngeal membranes are usually quite noticeably pale but still with whitish fibrinous exudate in some of the tonsillar crypts, and with small areas of congestion surrounding the crypt openings. Also, standing out brilliantly against the pale background of the tonsil and accentuating it may sometimes be seen a delicate tracery of engorged superficial vessels in the thin tonsillar mucous membrane.

THE ADENITIS

The adenitis itself is usually bilateral but it is not uncommon for one side to be much more involved than the other. The glands are hard, tender and sore on movement of the neck, which is usually moderately stiff, although less so in the very young. The swelling is sufficient to be quite obvious to the most cursory examination, palpation not being essential to diagnosis. Palpable glands are present in almost every case of acute tonsillopharyngitis, as was previously indicated, but adenitis of such slight extent is not meant to be within the purview of this paper.

Coming on as it so frequently does after an apparent improvement in the antecedent acute illness, the development of the adenitis is nevertheless usually closely enough associated with it to be its undoubted sequel. The usual elapsed time is seven days from onset to onset and this was true in one-half the cases in the series. The time element is not important, however, except that it must be sufficiently short to establish beyond reasonable doubt that the antecedent infection is the primary cause of the adenitis, and this must, after all, be left to the judgment of the individual clinician. Another characteristic of the adenitis which should be mentioned is its tendency in some cases to subside and recur. This apparent spontaneous improvement is often disappointingly deceptive and in certain instances the case may persist in this way for several weeks before being seen by the surgeon.

TEMPERATURE

The temperature will usually vary with the variation in swelling of the glands. It runs quite high as a rule, the highest peak temperature recorded in any case included in the series having been 105 F. The average for the series was 103.3. In this connection it must be borne in mind that these patients were not all in the hospital during the entire course of the disease and the highest temperatures were doubtless sometimes missed in that way. The chief characteristic of the temperature, however, is its extremely fluctuating type, reminding one of the temperature of general sepsis. This fluctuation of temperature may be as much as 4 or 5 degrees in a few hours, although a 3 to 4 degree fluctuation is more common. The characteristic temperature fluctuations are graphically shown in the accompanying charts. The average duration of fever before operation was 13.6 days, which means the length of time the patient manifested fever due to the adenitis up to the time tonsillectomy was performed. The average duration of fever after operation was 3.2 days.

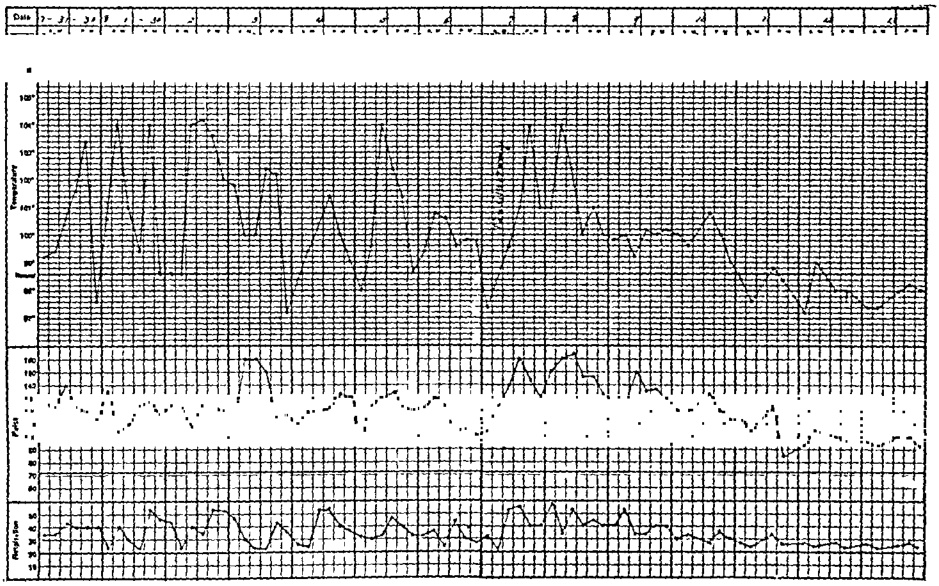

Chart 2.—Temperature in a second typical case of acute cervical adenitis. (Note that in this case the fever did not subside for forty-eight hours following tonsillectomy.)

PROSTRATION

The prostration is usually not marked until late in the disease and these little patients look surprisingly well during the remissions of the fever in the early stages. The rapid onset of anemia, however, results in a considerable amount of prostration later, which in the less vigorous child may be quite alarming at that stage. On the other hand, it is quite usual to have the parents remark that the patient does not seem sick except during the high febrile excursions and even then the depression may not be in proportion to the amount of fever exhibited. This is doubtless due to the essentially acute nature of the disease, coming on rather suddenly in an otherwise healthy child after an infection which has not been severe enough to undermine the child's strength and vitality especially and also to the fact that the elevation of temperature is not continuous but is characterized by remissions, giving the patient a rest from the deleterious effects of the fever and of the severe intoxication which is its cause.

ANEMIA

Anemia is one of the striking and constant characteristics of the disease. If the patient has been allowed to run along with the infection for two or three weeks the hemoglobin will be especially reduced, having been recorded in the series as low as 40 per cent and ranging from that up to as high as 78 per cent, the average for the series being 61$\frac{9}{11}$ per cent. The red cells are also reduced but not usually in proportion to the hemoglobin. This anemia is quite noticeable on looking at the patient's skin and mucous membranes, which are pale, especially the latter, frequently to such an extent that the pharyngeal mucosa does not show any sign of inflammation whatever. This may be a deceptive observation, although it is true that the acute manifestations in the phaynx have usually subsided materially before the adenitis supervenes. The anemia is properly treated by transfusion, which was done in this instance in three of the forty cases.

LEUKOCYTOSIS

Leukocytosis is marked, running as high as 34,100 in one case in the series, with an average for all of 17,177. A low leukocyte count is rarely seen, and the neutrophils are also frequently increased, up to 90 per cent and above. It seems impossible to form any definite opinion as to the presence or absence of pus from this indicator for the reason that the leukocytes respond so lavishly to the toxins without pus formation. The latter is likely to be indicated, however, when the white cells have apparently receded during the course of the disease and suddenly increased again, although even this may indicate only an increased extension of the inflammation to other previously uninvolved glands.

COMPLICATIONS

Complications frequently occur, of which the commonest is otitis media. This cannot properly be called a complication of the adenitis itself. It is undoubtedly a complication of the tonsillopharyngeal condition, which is the common antecedent of the two. Of this series thirteen had *otitis media* on one or both sides, and two of these ultimately developed surgical *mastoiditis* and were operated on, one on the eighth day and the other on the twenty-first day after tonsillectomy. This was in spite of the fact that the adenitis had subsided entirely in the meantime, which bears out the opinion, already expressed, that the otitis media had nothing whatever to do directly with the adenitis.

Nephritis, usually of the acute hemorrhagic variety, is the next complication in order of frequency. There were seven of these cases in the series and all were relieved by tonsillectomy, but the recovery was not so rapid as that of the glands, the kidneys taking from four to eighteen days to clear up entirely, or an average of 8.3 days for the series.

Pyelitis is encountered still less frequently but was seen as a complication in two cases of the series. When present, it can well account for some of the irregular temperature as it is impossible to differentiate the elevation of temperature caused by acute adenitis and by pyelitis. The pyelitis seems also to be relieved by removal of the cause of the adenitis, though the exact etiologic relationship of the primary and secondary infections to the kidney condition is difficult to ascertain.

No other complications were encountered in the series with the exception of pharyngeal abscess. In the series of cases there were three lateral pharyngeal abscesses. Two were drained at the same time the tonsils were removed; one two days before tonsillectomy. In these cases the adenitis was bilateral but was naturally worse on the side of the abscess. Their progress was just as satisfactory as in the cases without pus formation, with the exception mentioned later.

Suppuration of the glands is not an early development, rarely appearing earlier than one week after the onset of the adenitis and seldom even that soon. This sequel occurred in three of the cases, two of which were drained at the time the tonsils were removed, the third one week later. Even here the suppuration was thought to have begun before tonsillectomy was performed, as it was in one of the pharyngeal abscess cases and the suppurating gland was on the side of the abscess. It is my firm belief that this eventuality can be prevented in almost every case if the tonsils are removed soon enough, although if suppuration has already begun in the glands, even though only in its earliest stages, tonsillectomy will of course be of no avail and the case will go on to pus formation.

TREATMENT

Treatment by means other than tonsillectomy[4] I shall merely mention in passing. The usual rest in bed, local applications of ice and of various medicaments to the skin over the swollen glands or to the pharynx and tonsils, internal medication of various sorts, vaccines, light therapy and roentgen therapy have all been tried and found wanting. The use of x-rays may have its place in certain instances in which for some reason tonsillectomy is contraindicated or in previously tonsillectomized patients. Vaccines definitely do no good, and as for the other measures I can only say that my own impression is that their benefit is more imaginary than real and should be credited to the healing power of mother nature rather than to the particular therapy employed. However, should the condition yield to some of these or clear up spontaneously, it may not be necessary for the physician to face the necessity of making a decision regarding the advisability of removing the tonsils and adenoids. When, on the other hand, the disease manifests its usual characteristic of persistence in spite of all forms of treatment and the patient continues to have an irregular temperature, to lose weight and strength, to become rapidly anemic, and to behave generally in a manner discouraging both to the family and to the physician, it is time to consider something more efficacious in the way of treatment. At this stage the throat will be found to be almost entirely free from the usual evidences of acute inflammation and any hesitancy that might have restrained earlier action can be put aside without compunction. There is now no adequate reason for further hesitation, and the tonsils and adenoids should be removed without delay. It is true that often they may not look to be the source of the trouble, but their deceptive appearance must not be allowed to mislead.

It is scarcely necessary to mention that tonsillectomy does not confer immunity against cervical adenitis, although all authors agree that the disease occurs much less frequently in tonsillectomized children. However, the glands drain the pharyngeal mucous membranes as well as the tonsils themselves and may be involved from this source alone, in the absence of tonsils and adenoids. In these cases one is forced to resort to the less effective forms of treatment previously mentioned with the slow and unsatisfactory results familiar to all and so frequently encountered in just such cases.

When tonsillectomy is available as a form of treatment, it should be resorted to as early as possible after it is seen that the case is not progressing satisfactorily without it. In making this decision, too much time should not be allowed to elapse in the vain hope that the condition may yield to other forms of treatment, as it is only by early removal of the chief source from which the glands are being infected that the development of suppuration may be prevented. I am not deterred by the age of the patient, by the presence of fever, by the high white count and loss of hemoglobin or by the toxic condition. Neither does the fact of recent recovery from an acute tonsillopharyngitis serve as a deterring factor, so long as the throat is not then the seat of a frankly acute inflammation, which it never is by the time the glands are well established in their inflammatory reaction. It may be accepted as a fact that by the time the glands assume the proportions of an unmistakable acute adenitis the throat has subsided from its preceding acute stage and it is safe to operate. This statement is made in the full knowledge that these cases are practically always due to *Streptococcus hemolyticus*,[5] which organism has been obtained in cultures from the depths of the tonsils after removal in practically every case so studied, and from the pus from pharyngeal abscesses and suppurating glands when drained in this series of cases. There is a factor of local immunity established in the tissues on which the surgeon may depend and there seems to be no danger of increased general sepsis from the surgical intervention, as has been borne out by experience. In other words, it is hardly possible that if any great factor of risk existed in this procedure it could have been employed by one operator in a series of forty cases without a single suggestion of a mishap of any kind or description. Such, however, is the fact. I have had no more trouble from these cases so far as the operation or its sequelae have been concerned than from any other cases in my experience, whether selected risks or not.

[5] Howarth and Gloyne; Friedman and Greenfield; McClanahan, and Wagner (footnote 1).

In addition to these negative observations and to the lack of ill effects of any kind from the operation, the positive results are more than gratifying. In every case the improvement has been remarkable, in many almost miraculous. Occasionally, it is true, the glands have subsided slowly, over a period of one week, with some continuation of fever during that time. It might almost have been said that these patients would have made as good a recovery without the operation as with it, although observation of the course of the disease up to the time of operation convinced all observers that such would not have been the case. These were the least favorable results. The most spectacular were those in which the glands began to subside within twelve hours of the operation and within twenty-four hours were nearly normal, with normal temperature at the same time. From twenty-four hours to three days from the time of operation is the usual period required for subsidence of both glands and temperature, and the average time for the series was 3.2 days, as mentioned before.

CONCLUSIONS

If this paper has any justification whatever it is because it advocates and defends the principle that it is *safe*, not dangerous, to remove tonsils and adenoids during the height of an acute anterior cervical adenitis, and that such treatment is the most satisfactory in its results of any yet advocated for the condition. Hence, the paper defends the performance of a surgical procedure which is contrary to preconceived opinion, recognizing the fact that the operation may frequently be done in such cases in as short a time as two weeks, or even ten days, from the date of onset of an acute tonsillopharyngitis. This defies a certain prejudice known to exist against early tonsillectomy following an acute tonsillar infection. With this prejudice, as applied to cases in which definite therapeutic benefit promises to accrue, I do not agree. I believe that the experience of this series of cases amply supports the view that we should not permit preconceived opinion based more on theory than on experience to dissuade us from availing ourselves of whatever therapeutic measures are at hand when those measures seem to be and eventually prove themselves to be most valuable in the management of the particular condition with which we are dealing. The problem under consideration fulfils these requirements and for that reason I unhesitatingly recommend tonsillectomy as the treatment of choice in acute anterior cervical adenitis which follows a tonsillopharyngeal infection and fails to show definite signs of subsiding spontaneously within one week.

ABSTRACT OF DISCUSSION

Dr. William A. Defnet, Detroit: I am greatly encouraged in viewing this problem of surgical intervention for the relief of cervical adenitis in children. I am sure that all have had that mental hazard to overcome as to just when is the proper time to operate on these patients. As Dr. Baum has so aptly stated, it seems the logical and proper procedure to pursue under certain given circumstances. Of course, many are still governed by age-old conservatism and therefore still adhere to the old principle of doing tonsillectomy after all, or a greater amount, of the cervical disturbance has disappeared. I am still of the opinion that surgical intervention must not be regarded too enthusiastically in these cases, as my observation has been that there is danger of pulmonic infection, which may or may not be due to anesthesia or a combination of anesthesia and toxicity due to glandular involvement. Of course, this can be greatly overcome by the use of tracheobronchial anesthesia. I was surprised to note the small amount of upper bronchial involvement in the cases reported by Dr. Baum. In my observation, both in private practice and in the clinic, in these types of cases there is considerable involvement of the bronchial tract, and that factor has discouraged me from instituting surgical procedure; but this should not deter one from operating to relieve the subacute conditions or before permanent injury to other areas occurs. I agree heartily with Dr. Baum that, particularly in cases of adenitis following scarlet fever and in cases developing hemorrhagic nephritis, early surgical intervention should be instituted. Dr. Baum is to be congratulated on the careful and painstaking details which he has enumerated in his cases. He has opened a new field of thought for many in dealing with this perplexing problem.

Dr. Harold M. Hays, New York: I believe the author feels that acute tonsillopharyngitis with cervical adenitis is far more serious than acute tonsillitis in children, but I do not believe that he means to convey the idea that he would operate on children who are suffering from acute tonsillitis with a complicating adenitis. There is no doubt that tonsillopharyngitis cases are extremely serious and the complications do not stop there, as Dr. Baum states. Dr. Murray H. Bass listed various complications of a serious nature, among which were mesenteric inflammations, sometimes actual peritonitis, resulting from an inflammatory condition of the pharynx. If the patient is to get well quickly, it is necessary to do something more than carrying out the usual conservative treatment. I agree with Dr. Baum that the tonsils and adenoids should be removed regardless of fever or how severely ill the child is. This brings up another point of extreme importance: What shall be done with children who have different types of infection, cervical adenitis, acute infections of the ears and often mastoiditis? Which one of these is causing the fever? I recall having such a child under my care a number of years ago. The ear drums were incised but the cervical glands still continued inflamed. Whenever I was out of town another consultant was called in and the diagnoses ranged from erysipelas to subacute meningitis. By conservative treatment this child got well and finally the tonsils and adenoids were removed, but he would have recovered far more quickly if the tonsils and adenoids had been removed at an earlier date. Another serious complication of this type of infection is retropharyngeal abscess. Such cases are extremely dangerous. In one such case an external operation had been done but the tonsils had not been removed and therefore the infection continued. In another case an enormous abscess in the throat developed which was incised but the cellulitis was so great that there was considerable obstruction to breathing. The child was brought to the hospital, where the tonsil was enucleated. Unfortunately, the infection had spread to one of the larger arteries and on the following day a rupture of such an artery took place with immediate death. Lastly, I should like to make the point of removing the tonsils and adenoids at the time the mastoid operation is performed, particularly in those cases in which enlarged cervical glands are present.

Prof. Francesco Lasagna, Parma, Italy: Many years ago I studied the connection between the tonsils and adenoids and the lymph glands of the body. I did many experiments in anatomic pathology and also on animals, and it was possible to establish more readily than one would think the connection between the tonsils and the interior part of the throat. It is possible for infection that is not in the glands of the neck to have immediate connection with the glands in other parts of the body.

Dr. E. Lee Myers, St. Louis: Last winter I was seeing in consultation children that were thought not well enough to go to school, but not sick enough to stay at home, who had large glands in the anterior cervical region. The thing that struck me was the enlargement of the gland. I asked the family whether the child had been sick, and almost invariably I could get no history of acute tonsillitis. There was an epidemic of streptococcic sore throat and naturally I attributed it to that. The question came up as to when the tonsils should be taken out, and as these cases are always referred by the pediatrician or the family physician, the orthodox belief was encountered, as it always is, and it is impossible to get them to permit the removal of the tonsils. There were about six of these cases, and there were no bad results. I would say to Professor Lasagna that I am not familiar with the work of the Italian professor but I am glad to have him concur in the investigations of our confrère Dr. William V. Mullin, who has brought the same thing before us.

Dr. E. S. Strout, Minneapolis: I should like to ask the author what anesthesia he uses in the presence of acute hemorrhagic nephritis.

Dr. Harry L. Baum, Denver: The proper time to operate depends on the judgment of the surgeon. He must not be held back by the conservatism of the internist. The internist is afraid of surgery in the presence of acute symptoms. There is no difference between this and any other tonsil operation. One should go right ahead and take out the tonsils and adenoids the same as in any other case. The patient's temperature may be 100, 99 or 103 but that should not be allowed to stand in the way. Unless there is pharyngeal pus—which there will be in a small percentage of cases and which of course must be drained—there will be no difference in the operation from any other tonsillectomy, but the result is different because of the marked improvement in the patient's condition in the forty-eight hours following operation. This is really the pediatrician's problem primarily because we as laryngologists will not be called on to see the patients unless the pediatrician is educated to the need for surgery. Dr. Myers said he did not always have a clear history of antecedent tonsillitis in his cases of adenitis. Neither have I in all my cases but I have not included those cases in this series. All of these patients had a pediatrician in attendance, with the exception of a very few who had parents sufficiently intelligent to give a definite history of sore throat preceding the development of the tonsillitis. I want to say that this procedure is now common practice in Denver. The pediatricians there have learned its value and I believe that almost every one of them recognizes the situation when it arises, and calls on one of our laryngologists for his assistance. So that many more cases have been done than the small series on which I have based the paper. So also have many doubtless been done by men in other cities, but I have not chanced to come across them in the form of reports in the literature. Answering Dr. Strout's question regarding the anesthesia in cases of hemorrhagic nephritis, I use ether as a routine for these operations in all young children, even though they may have kidney complications.

Higher Education in America.—Science makes slow progress in the field of higher education, and for several reasons. . . . College administrators have not been overenthusiastic in their reception of the new day, partly for the reason that they find it disquieting. That which undermines tradition, questions established practice, or annihilates one's pet theories, is not likely to be received with open arms upon first aquaintance; and yet it seems clear that those who rely upon the methods and instruments of science are the ones who will soon, if they do not already, sit in the seats of power. . . . America has pursued her way in education, as in nearly everything else, stumbling here and halting there, moving forward in a zigzag fashion. She has found it difficult to set up remote goals and to strive to achieve them. She has compromised with the future and has pursued the paths of least resistance. . . . The most hopeful thing about the whole movement is that the experts in the various fields of learning are devoting themselves in increasing numbers to the study of their common problems. When the leaders in any field begin to question and to check their purposes, their work and their results, and when they call to their assistance experts in related fields, then and only then does there exist a basis for intelligent progress.—Kent, R. A.: Higher Education in America, Boston, Ginn & Co., 1930.

Clinical Notes, Suggestions and New Instruments

RELAPSING FEVER IN CENTRAL TEXAS

Burford Weller, M.D., and G. M. Graham, M.D., Austin, Texas

Relapsing fever, or African tick fever, prevailed in epidemic proportions in New York and Philadelphia during the year 1869; Meader has since reported five cases from Bear Creek Canyon, Colorado. Available literature discloses no other mention of this disease in the United States. Therefore, these cases may be of interest.

Four boys, aged about 16, explored a cave in the Colorado River valley, seventy-five miles above Austin. On emerging, they noticed attached to their legs several small ticks, which easily brushed off. Exactly six days from this time, three of the boys developed malaise, leg ache, headache, and elevation of temperature. The fever rapidly mounted to 103 or 104 F., the pains in the head and body became more severe, and a persistent sensation of chilliness, with nausea and vomiting, added to their discomfort. The blood showed a moderate leukocytosis, from 13,000 to 14,000 cells per cubic millimeter with a normal differential count and no malarial parasites. These symptoms continued for four days; then a macular rash appeared on all parts of the body, followed in a few hours by decline of the temperature to normal. During this decline, and for hours afterward, the patients were drenched by profuse sweats. The rash disappeared after twenty-four hours, leaving no discoloration.

When the fever subsided the patients, though weak, felt well, and remained so for an interval of from four to five days, when the second attack began.

This relapse was identical in all respects with the initial attack, except that it was milder and shorter, and there was no rash. The leukocyte count was slightly higher than before, the urine showed a trace of albumin, and the blood culture was negative.

The second afebrile interval varied in the boys from four to seven days, and was followed by a return of all the symptoms. During this third attack, actively motile spirochetes were found in the peripheral blood. Four-tenths gram of neoarsphenamine was given intravenously, resulting in the disappearance of all symptoms within eighteen hours.

Later, one of these patients relapsed after a ten day afebrile period and was given 0.6 Gm. of neoarsphenamine, with immediate effect. However, fourteen days after this, he again became sick, spirochetes were found in his blood, and more treatment was administered. Another was free from all symptoms for twenty-one days and then relapsed, necessitating more arsphenamine. The third patient has remained well.

During the investigation of the source of these cases, one of us (G. M. G.) visited the tick-infested cave. Several hours later, he found and removed one well fed tick from his body. On the seventh day following, he developed malaise, frontal headache, pains in the back and legs, and elevation of temperature. These symptoms steadily increased in intensity for eighteen hours, when spirochetes were demonstrated in the peripheral blood, and 0.3 Gm. of neoarsphenamine was given intravenously. This dose had no apparent effect; the temperature reached 104 F., and there was slight delirium, nausea and vomiting. The most unpleasant sensation was a penetrating, persistent coldness, more than a chilliness, which lasted twelve hours, during which the patient required several blankets and hot pads. A second dose of 0.6 Gm. of neoarsphenamine, eighteen hours after the first, had immediate effect, the temperature began to decline and within twelve hours was normal, and all symptoms had disappeared. As in the previous cases, this drop in temperature was accompanied by repeated, drenching sweats, causing intense thirst. There was no rash due to early treatment, and no relapse after three weeks.

The salient features of this infection seemed to be the persistent chilliness, the macular rash and the large amount of fluid lost by perspiration.

Inspection of the cave showed the floor covered with three inches of dry, powdery sand, which is literally alive with ticks, a handful of sand yielding thirty or forty of different sizes. They were identified by Major Wesley C. Cox, U. S. Army, Fort San Houston, as *Ornithodoro turicata*. The cave is frequented by goats and sheep; also probably wild animals, such as bats, foxes, skunks and rabbits. The distribution of these infected ticks, how long they have been infective in this locality, and whence came the infection are all interesting problems to be investigated.

Some of these ticks were applied to the shaven, abraded skin of three rabbits, allowed to feed for fifteen minutes, and then crushed and rubbed into the abrasions. Two of the animals died within twenty-four hours, probably from the extreme toxicity of the tick bites; the third became violently ill on the sixth day after inoculation, and, before death, actively motile spirochetes were found in the peripheral blood. Examination after the death of the animals showed nothing characteristic.

The spirochetes found in the blood varied in size; the typical ones were from 18 to 25 microns in length, having from ten to fifteen spirals. Their movements were rotary, backward and forward, and lashing. Some were so actively motile that the slide could not be moved quickly enough to follow them. Others were slower, and, as motion gradually ceased from some cause, would coil up, becoming almost unrecognizable. These coiled forms and tangles of two or more spirochetes were numerous in the peripheral blood. The definite, actively motile organisms were not very numerous in any of the cases, even at the height of the paroxysm, one spirochete to ten microscopic fields being about the average, though at times three or four could be found in one field. Never did they anywhere nearly approximate the number of erythrocytes, as described by some observers. They were best demonstrated by using a thin blood smear with dark field illumination, and, for study, could be kept alive in citrated blood for at least twenty-four hours. As yet, the strain has not been determined.

THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

RAYMOND HERTWIG, Secretary.

KEMP'S SUN-RAYED PURE TOMATO JUICE

Manufacturer.—The Sun-Rayed Company, Division of Kemp Brothers Packing Company, Frankfort, Ind.

Description.—A homogenized, pasteurized tomato juice seasoned with salt, packed by patented process.

Manufacture.—Vine ripened tomatoes from north central Indiana are used. They are compressed under constant pressure without any heating, beating or agitation. This procedure excludes so far as possible the presence of air which is destructive of vitamin C. The juice is passed through a straining screen.

The expressed juice and particles of pulp are homogenized to a permanent suspension. The product is seasoned to taste with salt, pasteurized by the flash method used in creameries, bottled or canned and again pasteurized.

Chemical Composition.—

(Proximate analysis)	Per Cent
Total solids	4.8
Ash	0 78
Sodium chloride	0.4
Fat (ether extract)	0.03
Protein (N × 6.25)	0 9
Crude fiber	0 1
Total carbohydrate (by difference) other than crude fiber	3.0

Calories.—

0.16 per gram.
4.5 per ounce.
72. per pound.

Vitamins.—The vitamin C content is but slightly less than that of fresh untreated tomato juice.

Claims of Manufacturer.—Sun-Rayed Tomato Juice is a refreshing beverage, rich in vitamins A, B and C, and valuable for infant feeding. Because of its low Calorie content it may be used in weight-reducing diets. It is recommended for the many uses to which tomatoes may be applied because of their valuable nutritive properties.

This tomato juice carries the red pulp in suspension, for which reason it has a much greater vitamin C potency than juices without the pulp. The vitamin C of the raw tomatoes used is only very little impaired by the manufacturing process.

WHITEFIELD' GENUINE ORANGE JUICE

Manufacturer.—Whitefield Citrus Products Corporation of California, Ltd., Fullerton, Calif.

Description.—An unsweetened, uncolored, sterilized orange juice in hermetically sealed bottles or jugs containing a partial vacuum of low pressure.

Manufacture.—The oranges are scrubbed by revolving brushes in the presence of hot water and steam. The peel is removed in peeling machines, care being taken not to cut through the "corky" layer. The peeled oranges are subjected to live steam and crushed in crushing machines, exposed parts of which are constructed of monel metal. The sieving screens are silver. The receiving tanks for the expressed juice are glass lined.

After the juice has been sieved, the subsequent processing is in an atmosphere of carbon dioxide. It is subjected to mild heat treatments and later sterilized by a special process. These treatments are designed to affect the natural vitamin values to a minimum degree. The juice is cooled to 70 F. and poured into bottles or jugs which are capped under reduced pressure of "3 inches mercury." The caps and containers are carefully heat-processed before use.

No artificial color or preservative is used. The elaborate processing tends to retain flavor and food values of the natural fruit. Utmost care is given to cleanliness and sanitation of plant and equipment.

Chemical Composition.—(Proximate Analysis)

Specific gravity 15 C./15 C	1.055
Total solids	14.2%
Acidity by titration as citric	1.4%
Hydrogen ion concentration as *p*H	3.4
Ash	0.42%
Alkalinity of ash (cc. N-acid to neutralize 1 gram)	11.1 cc.
Fat (ether extract)	0.1%
Volatile oils	0.01%
Protein (N × 6.25)	1.1%
Crude fiber	0.0%
Sucrose	0.0%
Reducing sugar as invert	10.1%
Total carbohydrates, by difference	11.1%
Artificial color	None
Chemical preservatives	None

Micro-Organisms.—

Yeasts (Sabouraud's Agar)	No growth
Bacteria (inoculated gelatin, 20 C. for 48 hours)	Negative
Bacteria (inoculated agar, 37 C. for 24 hours)	Negative
Dextrose agar (using pour) plates, 37.5 C., 48 hours	Negative
Litmus milk, 37.5 C	Unchanged

Vitamins.—

A + +
B (complex) + + +
C + + +

Calories.—

0.50 per gram
14 2 per ounce
227. per pound

Claims of Manufacturer.—The process of manufacture insures a uniform orange juice for use throughout the year. The nutritional value is practically that of fresh orange juice. As a result of production methods the resale cost approximates that of its equivalent in fresh oranges on the market.

ADDISON'S DISEASE

Appreciation of the importance of the suprarenal glands for life came primarily from the clinic and the necropsy room. Chronic suprarenal insufficiency was first described by Addison in 1855. "The disease develops in the third and fourth decade of life, usually insidiously, with adynamia and apathy. To these are added disturbances of the digestive tract (constipation alternating with diarrheas), pigmenting of the skin and mucous membranes: the patients succumb under a gradually increasing cachexia, not rarely with stormy terminal manifestations; autopsy almost always shows disease of both suprarenals, mostly tuberculous caseation." Thus reads the classic description of Addison's disease. The indispensability of the suprarenals has since been abundantly verified by extirpation experiments on various animal species.

In reviewing the physiologic literature of this subject, Britton [1] designates it as perhaps one of the most baffling facts to experimental physiologists today that all common laboratory animals from which the suprarenal glands (and cortical accessory tissues when present) have been removed, whether by the single or the two-stage operation, definitely die within a short period. The complete operation can be conducted with little trauma, in a comparatively short time—from ten to thirty minutes in the case of most animals—and the tissue loss per se is extremely small—roughly, one three-thousandth of the body weight. The most skilful surgical technic, Britton concludes, combined with optimal postoperative attention, has not lessened the 100 per cent mortality that follows, usually within a week or ten days, complete removal of the suprarenal tissues.

The discovery of a potent hormone, epinephrine, in the suprarenal medulla, and the proof of its secretion into the blood stream under certain types of physiologic provocation, naturally directed attention to this substance as an indispensable agent in living beings. However, the expectations in this respect have been completely shattered. On the one hand, removal of the suprarenal medullas without serious injury to the cortical structures is not a fatal operation; and, on the other hand, administration of epinephrine does not exhibit beneficial results in cases of suprarenalectomy. This hormone does not function in replacement therapy. Ablation of the suprarenal cortex is always fatal; and in recent months suitable extracts of the cortical structures free from epinephrine have been found to be uniquely potent in preventing the untoward effects of loss of the suprarenals.[2]

A new era in the study of the suprarenals seems at length to have been ushered in. Addison's disease is being reconsidered in the light of the newer physiologic studies. Wells [3] has recently pointed out that most cases of Addison's disease are associated with nearly complete destruction of the suprarenal glands, usually by tuberculosis, rarely by secondary neoplasms and amyloidosis. In such cases, no information is offered as to what part of the clinical picture depends on loss of cortical function and what part depends on destruction of the medulla. More instructive are the relatively infrequent cases in which there is found a selective destruction of the cortical elements alone. This condition, often inadequately called "atrophy" of the suprarenal glands, is apparently responsible for about one tenth of the cases of Addison's disease. Brenner,[4] who has surveyed records of many cases, drew the conclusion that the symptoms of Addison's disease occur only when most of the cortex is destroyed. The symptoms may be present, it is shown, even if the suprarenal medulla and the chromaffin tissues are normal; or again they are sometimes absent in cases in which there is almost complete disappearance of the chromaffin system. Incidentally, it may be recalled that in some cases Addison's disease has been described even when the suprarenal glands have apparently been intact. The possibility of hypofunction of the cortex, as well as the recognized difficulty in definitely diagnosing the condition, Britton asserts, must however be emphasized in this connection.

At the University of Chicago, Wells [3] has had opportunity in cases of Addison's disease to make postmortem examination of suprarenals exhibiting what has been termed "simple atrophy" involving an extensive, sometimes an almost complete, destruction of the epithelium of the cortex with less or practically no destruction of the medullary tissues. Cases of undoubted Addison's disease were not found in which the medulla was destroyed while the cortex was for the most part intact, although cases of such selective medullary destruction without the picture of Addison's disease have been observed. Therefore, the dependence of Addison's disease predominantly on destruction of the cortex of the suprarenal glands seems to be well established. Wells adds that the bilateral character of the lesion indicates its hematogenous origin. It is not associated with vascular lesions or occlusions. The resemblance both of the tissue damage and of the regenerative changes in the surviving cortical epithelium to the processes seen in diffuse toxic necrosis of the liver ("acute yellow atrophy") suggests to Wells that the suprarenal condition also is the result of a toxic necrosis by some poison selectively injuring the epithelium of the suprarenal cortex. The histories of the cases so far reported, however, give no satisfactory clue as to the source or nature of the hypothetic poison. It is a satisfying circumstance that human pathology—nature's experiments on man—and animal experimentation have so convincingly supplemented each other in relation to *the serious disorder described by Addison.*

IS THE COMMON COLD DUE TO A FILTRABLE VIRUS?

The common cold is one of the most devastating of human maladies—not that it leads to large numbers of deaths, but it does contribute largely to the type of morbidity classed as minor ailments. The mere discomfort caused by colds is itself of sufficient moment in relation to human happiness to warrant steps toward prevention or prompt relief. It has been said[1] that, if what seem to be "mere colds" were less commonly neglected, tuberculosis would more often be caught in its incipience and pneumonia and diphtheria would often be prevented. Furthermore, aside from the mere discomfort of such a minor ailment as a common cold, it may interfere with the customary routine that wage earning requires. Morbidity thus entails loss of income that runs into large figures when expressed in dollars and cents.

There have been many attempts to discover an infectious microbiotic agent responsible for the genesis of the common cold. The nasopharynx is the habitat of many varieties of bacteria in health as well as in disease, for none of which it has been possible to fix responsibility with any approach to certainty. The common laboratory animals are not afflicted with maladies that are closely analogous to the cold in man. Such animal diseases as distemper in dogs and snuffles in rabbits are quite dissimilar, from an etiologic point of view. When the higher apes were chosen for investigation, it was found that, in respect to organisms present, the flora of the upper respiratory tract resembled that in man to a surprising degree. Dochez, Shibley and Mills[2] of the Presbyterian Hospital, New York, were able to transmit characteristic common colds to them by instillation of a filtrable agent from human nasopharyngeal washings obtained within the first twenty-four hours of symptoms. The filtrates from healthy persons were not effective. Other investigators have reported the possibility of reproducing the common cold in human volunteers by introducing into their nasal passages small amounts of Berkefeld filtrates of the nasal secretions from individuals suffering from natural colds.

It has happened in most of these observations[3] that small gram-negative anaerobic bacteria could be cultivated from the ordinary Berkefeld filtrates. Recently Long and Doull[4] of Johns Hopkins University have attempted to transfer colds to healthy young women volunteers by means of filtrates containing the filter-passing anaerobes and by means of bacteria-free filtrates. These volunteers were placed in strict isolation and every precaution was taken to protect them from sources of natural infection. The experiments were *carried out during the months of June and July, 1930,* in which period the incidence of colds in Baltimore was at a low level. The nasopharyngeal washings were obtained during the first forty-eight hours of the natural colds. Positive developments were secured even with specially prepared filtrates that absolutely prevented the passage of either aerobic or anaerobic organisms. The observations seem to substantiate the conclusion that the infectious agent of acute upper respiratory infection (the common cold) is a filtrable virus.

GRAVITY AND THE CIRCULATION

There are surprising differences in the ease with which persons who are rated as being in excellent health and do not exhibit known circulatory defects make adjustments to certain changes in posture. Most of us are frequently altering our position from one pose to another. We arise, stand still, walk or exert ourselves in many ways without realizing that the consequent changes of bodily posture are attended with notable circulatory changes representing adjustments that make the variations in the body's position comfortable as well as physiologically effective. Not infrequently, healthy persons feel real discomfort, which may range from a vague sensation to acute dizziness or even fainting when they change from a reclining position to an upright posture. There is an evident circulatory embarrassment involved in this condition. Its nature is gradually becoming clearer as the result of careful investigation. An immediate factor that needs adjustment by the bodily mechanism is associated with the effect of gravity on the circulation. There will be the natural tendency for blood to stagnate in the lower parts of the body when the latter is shifted from a horizontal to a vertical position. To avoid this undesirable interference with the circulation, the vasomotor mechanism promptly tends to come into play in most persons. The first adjustment results in an increase in the rate of the heart accompanied by a rise of diastolic pressure and a narrowing of the pulse pressure. The systolic pressure shows no extensive change; it may rise or fall or be unchanged. The narrowing of the pulse pressure is of sufficient magnitude to suggest a much decreased output per beat for which the faster rate of the heart may not be able to compensate and thus to maintain the reclining circulatory minute volume. Presently, as a rule, there is a widened pulse pressure, particularly when muscular movements come into play. The pulse pressure in exercise is widened, mainly by a rise of the systolic pressure; in standing, the pulse pressure is narrowed as a result of the rise of diastolic pressure. In exercise the factors making for the return of blood to the heart are in evidence—augmented respiration, muscular movements—while in quiet standing these afford almost no help.

[3] Compare, for example the studies of G. B. Foster, Jr. (The Etiology of Common Colds, J. A. M. A. **66:** 1180 [April 15] 1916), and of P. K. Olitsky and J. E. MacCartney (Etiology of Typhus Fever, J. Exper. Med. **38:** 691 [Dec.] 1923).

[4] Long, P. H., and Doull, J. A.: Etiology of Acute Upper Respiratory Infection (Common Cold), Proc. Soc. Exper. Biol. & Med. **28:** 53 (Oct.) 1930.

Evidently the distress experienced by many persons during simple standing for even a few minutes is related to the failure of the circulation to supply sufficient blood to the higher nervous centers. Evidence of stagnation elsewhere has recently been obtained anew by Turner and her co-workers[1] at Mount Holyoke College. Observation of persons tilted at different angles while at rest on a movable holder suggested a distinct reflex for the response to gravity as contrasted with exercise, though both are characterized by increased heart rate. Exercise shows a widened pulse pressure, standing a narrowed pulse pressure. One of the early effects of standing without movement is the increase in the blood content of the legs. The average increment in leg size represents the temporary detaining in the part of the body concerned of about 4.6 per cent of the total blood in circulation, or between 200 and 300 cc. of blood. It also tends to stagnate in the abdominal region during standing. The effect can be lessened by such support as a bandage gives. Of course, posture and abdominal tonus are effective also, when they are suitably developed.

It is suggested by Turner that the vasoconstriction which serves to raise the diastolic pressure in standing and which shows signs of failure at the time of subjective discomfort is distinctly, as in hemorrhage, a compensatory mechanism. As in that case, the lessened output of the heart per minute as well as per beat is an essential element of the picture and is due to lessened return of blood from the veins. This output is still adequate for the needs of the brain in the many who stand successfully, but it is wont to fail more or less as the quiet erect position is held; and in poor subjects the time of successful functioning of the medullary centers may be brief indeed. It is of the greatest importance, Turner adds, to note that the methods which normally assist in returning blood to the heart are those which relieve this circulatory embarrassment in standing. Deep sighs are frequent in these uncomfortable persons; restless movements are often almost beyond their control; they stand much better during the abundant circulation which follows a meal when return from the digestive tract would be especially facilitated; they are aided by abdominal supports. If the prevention of blood "stagnation" in the upright posture may be secured by proper physical training, the prosecution of further studies as to the methods to be employed seems well worth while.

DIET IN CHRONIC GASTRIC ULCER

The successful treatment and healing of gastric ulcers involves many factors of uncertainty, reflected in the multiplicity of suggestions from therapeutists. For example, a recent writer asserts that the establishment of proper habits of eating, the avoidance of notoriously irritating articles of food which offend the gastric organ because of chemical, mechanical or thermal insults, the minimization of worry, strain and hurry—at least at meal times—the removal of infection from teeth, tonsils and accessory sinuses, the prevention of chronic constipation by regulation of diet and exercise, and the surgical removal of disease elsewhere in the abdomen are measures that tend to lower the incidence of ulcer. He adds that these are essential features in the treatment of ulcer whether surgery is employed or not.

The foregoing, by no means an antiquated statement, reads like a hygienic admonition that should favor recovery from many human maladies. It indicates how indefinite is our knowledge of this disease, of which even the etiology can scarcely be said as yet to have been ascertained. Experimentation is singularly difficult in human cases; hence it is proving to be a great advantage that characteristic gastric ulcer can be developed with considerable success in experimental animals. In the latter it has been observed that relative hyperacidity and hypernormal secretion such as are associated with partial pyloric stenosis are not necessarily such important factors in the delay of healing as was formerly assumed.

Mechanical factors, however, can delay the healing of an acute lesion of the gastric mucosa, and acid makes the ulcer more irritable or susceptible to bleeding. Fauley and Ivy[1] have further pointed out that coarse particles of food remain in the stomach longer than fine particles, which obviously results in more prolonged motor activity of the stomach and increases the trauma to an acute lesion of the mucosa. This would be pronounced in a patient with pylorospasm. In studies at the Northwestern University Medical School, Chicago, they have demonstrated that certain types of acute experimental lesions of the gastric mucosa are definitely harmed by a "rough" diet. For instance, a simple ulcer of the rabbit's stomach produced by excision heals within thirty days, irrespective of the consistency of the diet. A similar ulcer, but with a silk suture in its base, will heal if the rabbit is fed a soft diet but will tend to become chronic if the rabbit is fed a rough diet. Therefore Fauley and Ivy conclude that in chronic ulcer in man a soft diet would facilitate the healing of the ulcer, which confirms clinical experience and supports the use of a diet of the character of that employed in the generally accepted therapeutic procedures for gastric ulcer.

Current Comment

CULTURE OF TUBERCLE BACILLI

Improvement in bacteriologic technic is bringing the culture of tubercle bacilli well into the range of everyday practice. It is already two years since Corper[1] showed the superiority of his cultural method over guinea-pig inoculation. In a recent report from the research laboratories of the Municipal Tuberculosis Sanitarium, Chicago, Sweany and Evanoff[2] describe a modification of Dorset's egg medium, cream being used instead of glycerin, which they have found superior to Corper's medium especially in growing the bovine bacillus. Von Húth and Lieberthal,[3] reporting from the Royal Hungarian Pázmány Péter University at Budapest, also prefer a modified egg medium to Corper's medium. They used the modification of Hohn, in which meat extract, sodium chloride and peptone are added and they found that this medium grew colonies in from eight to twenty days, whereas the glycerin-potato medium, inoculated at the same time with the same material, showed colonies in from three to five weeks. In several cases, they say, the cultures were positive when the guinea-pig test was negative. In these cases there was minimal functional defect in the diseased organ (all their cultures were made for suspected renal tuberculosis). Operation disclosed incipient tuberculosis of the kidney. There is still a good deal of disagreement as to the right method to be used to destroy contaminating organisms. Corper abandoned 3 per cent hydrochloric acid in favor of 6 per cent sulphuric acid. Sweany and Evanoff still prefer 3 per cent hydrochloric acid and find that 12 per cent sulphuric acid is "entirely too strong." Von Húth and Lieberthal, on the other hand, found the 10 per cent sulphuric acid recommended by Hohn to be of insufficient strength and used a 15 per cent solution as prescribed by Lowenstein. They found this strength sufficient to exclude all contaminators except molds without injuring the tubercle bacilli. Indeed, the latter were found so resistant to this strong mineral acid that they survived exposures four times the length of the customary twenty minutes. Von Húth and Lieberthal, unlike the workers in the Municipal Tuberculosis Sanitarium, found no difficulty in growing the bovine type of bacillus on glycerin-potato. It is thus evident that a final technic for cultures cannot be established, though it is equally clear that any competent bacteriologist can now find the tubercle bacillus more quickly and more accurately by culture than by inoculation.

THE PROPHYLAXIS OF COCAINE AND ALLIED INTOXICANTS

Since the publication by the chairman[1] of the Committee for the Study of Toxic Effects of Local Anesthetics of the American Medical Association of the conclusions of that committee in 1924, there has grown up a literature on the prevention of cocaine intoxication by the use of depressant drugs and particularly of the compounds of barbituric acid. Two years ago, Guttman[2] presented an impressive series of 391 operations under cocaine anesthesia with only two reactions, one of which was attributed to hysteria and the other to faulty technic in the administration of the prophylactic (0.2 Gm.) dose of phenobarbital. This may be compared with a previous series of 416 operations under cocaine, but without the prophylactic, in which no less than 19 per cent of the patients showed evidence of cocaine intoxication. Others have reported similar results. Martin[3] reported that the use of 0.6 Gm. of soluble barbital given by mouth about one hour before operation under procaine anesthesia will prevent the development of serious toxic symptoms in most instances. He added that investigation of the subject was far from complete or conclusive and recommended an independent study of the different salts of barbituric acid to determine their individual efficiency in the detoxication of local anesthetics. Such a study is now reported from the department of Pharmacology of the University of Wisconsin.[4] The minimal tolerated and the minimal lethal doses of cocaine, procaine or butyn for rabbits were determined without protection and after the administration of various depressants. The depressants found effective and in the order of their efficacy are urethane (ethyl carbamate), chloral hydrate, paraldehyde, barbital, phenobarbital, and isoamylethylbarbituric acid, the last named being the most effective. This order also represents the depressant power of the drugs as tested by irritation after administration of each. The investigators find that there are two types of intoxication into which clinical cases may be divided. One has a prolonged course and death results from primary respiratory failure; the other has a short course and death results from primary cardiac failure. The first type is reproduced experimentally by subcutaneous injection of cocaine, the second type by intravenous injection. Against this second type of intoxication the depressants, as might be expected, are valueless. The practical conclusions to be drawn from the latter observation are obvious. Although cocaine, procaine and butyn were the only local anesthetics used in this study, the authors remark that the action of other local anesthetics having similar chemical composition is likely to be affected by the depressants in a similar way.

Association News

WATCH FOR THE COLORED ENVELOP NEXT WEEK

The envelop remittance form for subscription and fellowship dues inserted in The Journal last year proved so popular that *the same type of reminder will again be placed in each copy of* next week's issue of The Journal. This colored slip is, in effect, a statement for the *1931* dues, which are payable in advance. When folded, the slip will form a perfect envelop bearing on its face the return address and the business reply imprint, which makes a *postage stamp unnecessary*. Members and Fellows will find this slip a most convenient method for remitting their 1931 dues.

CONTRIBUTIONS FOR PERSHING HALL

The response to the editorial last week soliciting contributions for the medical salon in Pershing Hall as a memorial for physicians who served and for those who died in the war has been prompt. As The Journal goes to press, the first day's mail brought contributions in the following order:

William H. Woglom, M.D., New York
J. F. Hammond, M.D., Chicago
W. R. Bennett, M.D., San Antonio, Texas
Lewis A Conner, M.D., New York
Milton DeWitt Pollock, M D., Decatur, Ill.
A W. Hornbogen, M.D., Marquette, Mich.
Israel Weinstein, M D., New York
Charles H. May, M.D., New York
James W. Kelly, M.D., Chicago
Robert Lee Hall, M.D., Pocomoke City, Md.
C. W. Lockhart, M.D., Mellen, Wis.
W K. Mittendorf, M.D., New York
I. S. Egan, M.D., Julesburg, Colo.
Olin West, M.D., Chicago
Morris Fishbein, M.D., Chicago
W. F. Wilson, M.D., Lake City, Minn.
W. T. Clark, M.D., Janesville, Wis.
J H. Walsh, M.D., Chicago
James J. Snipes, M.D., Lincoln, Neb.
Frank L. Truitt, M.D., Indianapolis
Edward B. Heckel, M.D., Pittsburgh
P. J. H. Farrell, M.D., Chicago
Scott Gomien, M.D., St. Louis
E. J. Goodwin, M.D., St. Louis
Emil C. Robitshek, M.D., Minneapolis
J. M. Sokol, M.D., Spencer, Iowa
E. Sanborn Smith, M.D., Kirksville, Mo.
A. A. Passer, M.D., Olivia, Minn.

The contributions vary in amount from $1 to $25. The total sum received is $102.50. It is proposed to acknowledge contributions as they come in and it is hoped that various individuals, medical societies and other organizations will make their collective subscriptions promptly so that the total sum needed will soon be realized.

MEDICAL BROADCAST FOR THE WEEK

American Medical Association Health Talks

The American Medical Association broadcasts at 10 a. m. on Monday, 10:15 on Tuesday, 10:30 on Thursday, and 10 on Saturday, over Station WBBM (770 kilocycles, or 389.4 meters).

The program for the week is as follows:

December 15.	Preventing Death from Cancer.
December 16.	The Cause and the Cure.
December 18.	Preventing Diseases of the Teeth and Gums.
December 20.	A Full Time Health Officer.

Five minute health talks may be heard over the Columbia Broadcasting System daily except Sundays and holidays, from 12 to 12:05 p. m.

The program for the week is as follows:

December 15.	Christmas Shopping.
December 16.	Personal Preferences.
December 17.	Why People Get Sick.
December 18.	Sanity in Driving.
December 19.	When You Catch Cold.
December 20.	Too Much Coddling.

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest: such as relate to society activities, new hospitals, education, public health, etc.)

ALABAMA

State-Wide Campaign Against Tuberculosis.—The first of the antituberculosis clinics to be held by the state health department in cooperation with the county physicians and the county health department was held, November 3, in Montgomery. This marks the opening of the state-wide campaign against tuberculosis, in which an effort will be made to locate all tuberculous persons and provide needed treatment. The work will be under the direction of Dr. Daniel G. Gill, Montgomery, head of the bureau of communicable diseases of the state health department, assisted by Drs. S. B. McPheeters and Thurston D. Rivers, who will have charge of the clinics. The next clinic will be held in either Lee or Macon County. The purpose of the clinic is diagnostic and the patients are referred for treatment to practicing physicians or to county health officers. In 1929 there were 2,248 deaths in Alabama attributed to this disease, and 1,428 were of Negroes. It is estimated that there are between 20,000 and 25,000 cases in the state at present.

COLORADO

Revocation of License Upheld.—A Colorado district court recently upheld the action of the state board of medical examiners in the revocation of the license of Dr. Clyde Leslie Van Patten. The license was revoked, Oct. 1, 1929, on charges of unprofessional and dishonorable conduct and habitual intemperance in the use of alcoholic drinks. Van Patten was graduated in 1911 from the Hahnemann Medical College and Hospital, Chicago, which is now extinct.

Society News.—The Medical Society of the City and County of Denver was addressed, November 18, by Drs. Nolie Mumey and James Rudolph Jaeger, both of Denver, on "Sarcoma of the Small Intestine" and "Fracture of the Skull," respectively. Dr. M. Weinberg of the Pasteur Institute, Paris, France, addressed the society, November 25, on "Serotherapy of Anaerobic Infection." The society was addressed, December 2, by Drs. William B. Yegge on "Polycythemia"; George B. Kent, "Traumatic Rupture of the Esophagus with Mediastinal Abscess"; Philip Work, "Multiple Fat Emboli"; Frank B. Stephenson, "Traumatic Subperiosteal Hemorrhage in an Infant: X-Ray Study"; Wilfred S. Dennis, "Postpyloric Obstruction of the Stomach with Dilatation." A motion picture was presented on "Traumatic Surgery of the Extremities."

ILLINOIS

Chicago

Society News.—Dr. Gerhardt von Bonin, Leyden, Netherlands, addressed the Medical Research Club of the University of Illinois College of Medicine, November 12, on "The Skulls of the Easter Islanders," and William C. Austin, Ph.D., and Messrs. C. J. Smalley and M. I. Sankstone, on "Changes of *l*-Arabinose and *d*-Xylose Under the Influence of Dilute Alkali."——The Chicago Neurological Society was addressed, November 20, by Dr. Karl A. Menninger, Topeka, Kan., on "Psychoanalytic Aspects of Suicide."——Drs. Herman L. Kretschmer and Norris J. Heckel, among others, addressed the Chicago Urological Society, November 20, on "Atonic Dilatation of the Bladder."——The Chicago Gynecological Society was addressed by Drs. Edward L. Cornell, Leon J. Goodman and Mabel M. Matthies on "Trichomonas Vaginalis: The Incidence and Treatment," and Dr. David S. Hillis, "Diagnosis of Contracted Pelvis by Impression Method"; Dr. Irving F. Stein and Elizabeth J. Cope presented a preliminary study on *Trichomonas vaginalis*.——"Ligation of the Tail of the Pancreas in Juvenile Diabetes" was the subject of Dr. Géza de Takáts before the Chicago Society of Internal Medicine, November 24, and "Variability of Reflex Responses" that of Dr. Stephen W. Ranson; Drs. Philip O. Daly and Solomon Strouse spoke on "The So-Called Medical Complications of Pregnancy."——The Chicago Society of Industrial Medicine and Surgery was addressed, November 5, by Dr. James A. Britton on "Chest Injury and Lung Disease."——Clarence W. Muehlberger, Ph.D., addressed the Chicago Medicolegal Society, November 4, on "The Estimation of Alcoholic Intoxication."——At the fifteenth annual meeting of the board of governors of the Institute of Medicine of Chicago, December 3, the following officers were elected: chairman of the board, Dr. Ludvig Hektoen; president, Dr. Otto L. Schmidt; vice president, Dr. Charles E. Kahlke; secretary, Dr. George H. Coleman, and treasurer, Dr. John Favill. "Personal Experiences as Medical Examiner" was the subject of an illustrated address given by Dr. George Burgess Magrath, Boston; the presidential address was given by Dr. George E. Shambaugh on "The Problem of Deafness."

INDIANA

Society News.—Dr. Edwin Kime, Indianapolis, addressed the Rush County Medical Society, November 10, on "Diathermic and Quartz Light Treatment."——Dr. Leonard G. Rowntree, Rochester, Minn., addressed the St. Joseph County Medical Society, November 19, on "Nerve Operations for Hopeless Cases of Rheumatism."——Dr. James H. Stygall and Dr. Jewett V. Reed addressed the Indianapolis Medical Society, December 9, on "Childhood Lung Conditions" and "Recent Methods of Treatment of Head Injuries," respectively.——The Montgomery County Medical Society was addressed at Crawfordsville, November 20, by Drs. Rollin H. Moser and Alois B. Graham, both of Indianapolis, on "Cardiospasm" and "Anorectal Diseases," respectively.——"Safety Factors in the Technic of Spinal Anesthesia" was the subject of Dr. Floyd T. Romberger, La Fayette, before the Elkhart County Medical Society at Elkhart, November 13; he addressed the Indianapolis Medical Society, December 16, on the same subject.——Drs. Edmund M. Van Buskirk and Abraham J. Sparks, both of Fort Wayne, addressed the Adams County Medical Society, November 14, on "Brain Tumors" and "Genito-Urinary Diagnosis," respectively.

MARYLAND

Society News.—Sir D'Arcy Power, London, England, visiting lecturer, Institute of the History of Medicine of Johns Hopkins University School of Medicine, Baltimore, addressed the Medical and Chirurgical Faculty of the State of Maryland, December 5, on "The Rise of Medical Education in England"; Drs. James F. Mitchell and Oscar B. Hunter, Washington, D. C., spoke on "Progressive Gangrene of the Abdominal Wall."——Physicians who have served the Baltimore City Medical Society as presidents during the first quarter century of its existence will attend the December 19 meeting of the society in a group; "A Consideration of Leprosy in the United States" and "Leprosy in Hawaii" will be the subjects of Drs. William W. Ford and James T. Wayson, Honolulu, Hawaii, respectively.

Lectures on Medical History at Johns Hopkins.—Lectures on various phases of the history of medicine have been announced for the current academic year at the Institute of the History of Medicine of Johns Hopkins University. Dr. Fielding H. Garrison, resident lecturer in the history of medicine and librarian of the Welch Medical Library, is giving a seminar course in medical literature and bibliography, which began October 16 and will continue until Jan. 22, 1931. Beginning March 26, Dr. Garrison will present a series of seven lectures on national medicine, embracing Russian medicine under the old régime and under the Soviet system, and Spanish, Scandinavian, Italian, Germanic and French medicine. These will continue until May 7, 1931. Dr. Stephen d'Irsay, associate in the history of medicine, is scheduled for courses on the history of physiology, the history of universities and ancient and medieval scientific textbooks. Dr. John Rathbone Oliver, associate in the history of medicine, will give an introductory course to the history of medicine for students who wish a survey of the whole field. Dr. William H. Welch, professor of the history of medicine, will give weekly lectures during January, February and March on topics to be announced later. The series of lectures now being presented by Sir D'Arcy Power, honorary librarian of the Royal College of Surgeons, England, announced in The Journal, November 29, is a part of this program.

MASSACHUSETTS

Society News.—The Suffolk District Medical Society was addressed, November 19, by Dr. Samuel N. Vose on "Intravenous Urography in Bladder Neck Obstruction."——Dr. Solomon Strouse, Chicago, addressed the Greater Boston Medical Society, December 2, on "Medical Complications of Pregnancy."——"Diagnosis of Colonic Lesions as Seen by the Fluoroscope and Plates" was the subject of Dr. Laurie B. Morrison, Boston, before the Essex South District Medical Society, December 3.——Dr. Elliott P. Joslin, Boston, delivered the third of a series of monthly lectures before the William Harvey Society of Tufts Medical School, December 12, on "The Carbohydrates in the Body." The second lecture was given by Dr. Howard W. Haggard, New Haven, Conn., November 14, on "Medicine Through the Ages." Dr. George H. Bigelow, Boston, will deliver the fourth lecture, January 9, on "Adult Life."

Appointments at Harvard.—The following appointments, among others, were recently announced for one year from September 1:

Dr. Gordon Douglas Atkinson, assistant in genito-urinary surgery.
Dr. Joseph Seaton Barr, assistant in orthopedic surgery.
Dr. Stewart Hilton Clifford, assistant in pediatrics and child hygiene.
Dr. John Godwin Downing, assistant in dermatology and syphilology.
Dr. Ives Hendrick, assistant in psychiatry.
Dr. Robert Ritchie Linton, assistant in surgery.
Dr. Stephen James Maddock, assistant in surgery.
Dr. Sumner Mead Roberts, assistant in orthopedic surgery.
Hawley Seager Sanford, S.B., assistant in anatomy.
Dr. Harvey Spencer, assistant in pediatrics and child hygiene.
Dr. Jessie Reed Cockrill, research fellow in medicine.
Dr. Norman Easton Freeman, research fellow in physiology.
Dr. John Heysham Gibbon, Jr., research fellow in surgery.
Dr. Robert Allan Phillips, research fellow in physiology.
Dr. Arturo Rosenblueth, research fellow in physiology.
Dr. Oliver Cope, assistant in surgery.

MICHIGAN

Physician Honored.—Dr. George B. McCallum, Monroe, 75 years old, was made an honorary life member of the Michigan State Medical Society at a meeting of the Monroe County Medical Society, November 20. Dr. McCallum was born in Ann Arbor in 1855, was graduated from the University of Michigan in 1880, and after a year of postgraduate study at Columbia University began the practice of medicine at Monroe, according to the Monroe *News*. Dr. James D. Bruce, Ann Arbor, represented the state society in conferring the honor on Dr. McCallum.

Student Health at University of Michigan.—Only 23 per cent of the new students at the University of Michigan were found free from physical defects, it has been announced. More than half were found to have defects that were not serious and the remaining 20 per cent had defects that required speedy attention. During the past year 10,536 dispensary calls were made by the students, as compared with 7,502 the previous year, it is reported; the number of infirmary patients increased from 138 to 157; room calls from 152 to 188, and prescriptions filled mounted from 1,300 to more than 1,500. The appointment of a full time mental hygienist resulted in an increase in mental hygiene conferences from 87 to 696.

Society News.—The fourth annual conference of the heart committee of the Tuberculosis and Health Society of Detroit and Wayne County was held, November 14; the general subject was "The Cardiac Child, Its Problems, Present and Future"; the speakers were Dr. Ray E. Logan, Detroit, "The Cardiac Child at School"; Dr. Robert L. Novy, Detroit, "Developing a Normal Personality"; Marjorie M. Kinney, New York, "How to Use the Clinic, the Social Worker and Nurse," and John J. Lee, Lansing, "Planning for the Future—Vocational Guidance."——Dr. Raphael Isaacs, Ann Arbor, addressed the Kalamazoo Academy of Medicine, November 18, on "The Different Kinds of Anemias."——Dr. Don H. Duffie, Central Lake, addressed the Calhoun County Medical Society, November 4, on "Management of Diabetes."

MINNESOTA

Masseuse Sentenced on Charge of Abortion.—The Minnesota State Board of Medical Examiners reports revocation of the massage license of Olga Stenhoff, December 2. The defendant was convicted, December 3, in the district court of Hennepin County, when she pleaded guilty to the charge of abortion and was sentenced to serve a term not to exceed two years at the Women's State Reformatory at Shakopee, where she is now imprisoned.

Society News.—Drs. A. I. Arneson, Starbuck, and Charles L. Scofield, Benson, addressed the West Central Medical Society, Morris, October 8, on "Blood Chemistry" and "The Relation of Physicians to the State Board of Health," respectively.——"Gastro-Intestinal Diseases of Children" was the subject of Dr. Roger L. Kennedy, Mayo Clinic, Rochester, before a recent meeting of the Houston-Fillmore County Medical Society at Harmony——Dr. Myron O. Henry, Minneapolis, addressed the Scott-Carver County Medical Society, October 14, at Belle Plaine on fractures, and presented motion pictures of Boehler's method of treating fractures.——The Washington County Medical Society was addressed in October by Dr. Owen H. Wangensteen, Minneapolis, on "Cancer of the Stomach."——Dr. Samuel H. Boyer, Duluth, among others, addressed the Red River Valley Medical Society, October 9, at Warren, on "Some Phases of Organized Medicine."——Dr. Rood Taylor, Minneapolis, opened the second clinical course of the Lyon-Lincoln County Medical Society at Marshall, October 1, with a discussion of pediatrics.——At the regular meeting of the Minnesota Academy of Medicine at Minneapolis, December 10, Dr. James A. Johnson spoke on "Acute Mechanical Obstruction of the Lower Bowel," and Dr. Frank E. Burch, St. Paul, on "Operative Treatment of Squint by the Tucking Method."

MISSISSIPPI

Society News.—Papers were delivered before the Issaquena-Sharkey-Warren Counties Medical Society, November 11, by Drs. R. H. Foster, Anguilla, on "Psychiatry for the General Practitioner"; George M. Street, Vicksburg, "Cholecystitis," and Guy C. Jarratt, Vicksburg, "Some Emergencies of the New-Born."——A joint meeting of the Fifth District Medical Society of Louisiana and the Issaquena-Sharkey-Warren Counties Medical Society was addressed at Vicksburg, December 9, by Drs. William W. Butterworth, New Orleans, on the occurrence of syphilitic nephritis in infancy and childhood; Virgil S. Counseller, Rochester, Minn., "Anatomy and Surgical Treatment of Undescended Testicle," and James G. Carr, Jr., Chicago, "Cardiac Pain: Characteristics and Significance."——"Our Obligation to Organized Medicine" was the subject of Dr. Charles W. Patterson, Rosedale, in an address before the Clarksdale and Six Counties Medical Society, November 5, at Clarksdale, and "Treatment of Normal Breech Presentation" that of Dr. Dolph V. Galloway.

NEW JERSEY

Society News.—The forty-seventh annual meeting of the Cape May County Medical Society was addressed, November 6, by Dr. James T. Rugh, Philadelphia, on "Focal Infections and Their Interest to the General Practitioner."

Miscellaneous Stores Sell Medicines.—More than 400 meat, grocery, confectionery, cigar and other retail stores in four southern counties in New Jersey were found to be selling medicines and druggists' supplies so far below standard quality as to be a menace to public health, investigation by the New Jersey Board of Pharmacy has revealed. Many of the dealers questioned are said to have told the investigators that salesmen for wholesale or manufacturing houses had urged them to carry druggists' supplies and had informed them that sale of the products was legal. The pharmacy board will probably introduce bills into the next session of the state legislature whereby manufacturers would be made liable if their customers are not registered pharmacists, according to a statement reported in the New York *Times.*

NEW YORK

Sanatorium for Variety Artists.—A new sanatorium at Saranac Lake, backed by the entire vaudeville and motion picture industries, to be known as the National Variety Artists' Sanatorium, was formally opened to the medical profession of the surrounding area, November 20. Dr. Edgar Mayer is medical superintendent.

Fifty Million Dollars for State Institutions.—A bond issue of $50,000,000 for new construction at state hospitals for the insane, schools for mental defectives and epileptics, state prisons and reformatories was approved by a vote of 6 to 1 at the November election. In New York City the vote was 14 to 1. Elihu Root was honorary chairman, and Cornelius N. Bliss chairman of the campaign.

New York City

Blood Transfusion Service.—The Donor Bureau, sponsored by the New York Academy of Medicine, now has a twenty-four hour service with an average of more than 300 calls a month. The bureau is serviced by about seventy hospitals as well as many physicians, and it has a list of 800 donors, each one carefully classified as to group and none of them professional. The donor must be subject to call day or night and must undergo a rigid physical examination at the time of registration and again before each transfusion. Many soldiers at Fort Hamilton are listed and make excellent donors on account of selection and careful physical supervision. In addition to supplying qualified donors for transfusion, the organization supplies serums for blood grouping and performs blood grouping on request. The blood transfusion service has undergone several changes in organization since it was started in 1927. Since the Donor Bureau has been sponsored by the academy of medicine, its service has steadily increased from about 125 calls a month to more than 300.

Conference on Sight Conservation.—During a recent conference of the National Society for the Prevention of Blindness, held jointly with the National Organization for Public Health Nursing, special discussions were made on the conservation of vision in school children. It was reported that 1,000 school children in New York City had seriously defective vision and had failed to receive the attention their handicap requires. Request for nineteen additional sight-saving classes had been made, but the board of education had been unable to meet this request on the ground of retrenchment, creating in the waiting list of 1,000 pupils a feeling of inferiority. There are now seventy-nine sight-saving classes in New York City, accommodating 1,450 pupils, many of them in the elementary grades. There is urgent need for twenty-one additional classes in the elementary grades, and for twenty-nine classes in the junior and senior high schools. Dr. Jules L. Blumenthal, director of the city bureau of child hygiene, said the health department in its eleven clinics had examined 16,256 children in 1929, and 10,905 prescriptions for glasses had been written.

OHIO

Hourly Nursing Service in Columbus.—Hourly nursing service at a rate of $2 for the first hour and 75 cents for each additional hour was recently instituted at Columbus through the official nurses' registry. The registry has also a special fee for obstetric cases when a nurse's care is desired in the home only during delivery and for a short time afterward.

Physician Honored.—Dr. Joseph Henry Todd, Wooster, was tendered a banquet, November 11, by members of the Wayne County Medical Society. Dr. Todd, who is 94 years of age, was presented with a certificate making him a life member of the society. Dr. Robert C. Paul, Wooster, secretary of the society, was toastmaster, and the speakers included Judge Hiram B. Swartz and Drs. Lincoln A. Yocum and John G. Wishard.

Society News.—Dr. John O. Polak, Brooklyn, N. Y., addressed the Columbus Academy of Medicine, November 17, on "Relative Value of Surgery and Irradiation in Cancer of the Uterus"; this was the annual D. Tod Gilliam memorial lecture.——The Maumee County Medical Society was addressed, November 11, by Drs. Floyd P. Allen, Cincinnati, and Clarence S. Ordway, Toledo, on "Traumatic Injury and Treatment to the Perineal Region" and "Traumatic Surgery," respectively.——Dr. William De W. Andrus, Cincinnati, addressed the Butler County Medical Society, November 12, on "Metabolic Rate Aspects of Thyroid Disease," and Dr. Mont R. Reid, Cincinnati, on "Medical and Surgical Treatment of the Thyroid."——The Warren County Medical Society acted as host to physicians in Highland, Fayette, Clinton and Green counties, November 12; papers were delivered by Drs. Alonzo B. Brower, Dayton, on "Classification and Later Day Treatment of the Anemias," and Harry R. Huston, Dayton, "Blood Typing and Transfusions," and Elmer R. Arn, Dayton, "Surgical Indications in Anemia."

PENNSYLVANIA

Society News.—Dr. Damon B. Pfeiffer, Philadelphia, addressed the Erie County Medical Society, November 4, on "Facts and Fancies Concerning Carcinoma of the Colon."——The fifteenth Mellon Lecture was delivered in Pittsburgh by Dr. Torald H. Sollmann, professor of pharmacology and materia medica and dean of the Medical School of Western Reserve University, December 5, on "Clinical Excretion of Mercury." This lecture is sponsored by the Biological Society for Research of the University of Pittsburgh.

Philadelphia

Research Clinic for Tumors.—A research clinic for the study of tumors is to be inaugurated, January 1, at the Jewish Hospital under the direction of Dr. Leon Solis Cohen. The clinic, which is said to be financed by an anonymous friend of the hospital, will include departments of radiology, clinical research, experimental research and education, and a dispensary for the reception and care of patients. Prominent among its activities will be an educational project to encourage early diagnosis and to urge sufferers to submit to early operation if it is advised by competent surgeons. Dr. Nathan Blumberg will supervise the department of clinical research and Dr. Benjamin Gruskin, the department of experimental research. Dr. Cohen will take charge of the department of radiology.

Society News.—Dr. Roy B. Henline, New York, addressed the Philadelphia Urological Society, November 24, on "Paravertebral Anesthesia."——A symposium on industrial medicine was conducted before the Philadelphia County Medical Society, December 10; Dr. John J. Moorhead, New York, spoke on "Practice of Traumatic Surgery"; Drs. William Bates, Eldridge L. Eliason and George Morris Piersol took part in the discussion.——The Philadelphia Academy of Surgery was addressed, December 1, by Drs. Benjamin Lipshutz and George M. Dorrance on "Carbuncle of the Kidney" and "Cecal Drainage in Acute Suppurative Appendicitis," respectively.——Dr. Joseph C. Birdsall addressed the Philadelphia Medical Examiners' Association, December 1, on "Significance of Pus in the Urine."——The Obstetrical Society of Philadelphia was addressed, December 4, by Dr. Arthur H. Curtis, Chicago, on "Surgical Correction of Pelvic Lesions Incident to Childbirth."

SOUTH DAKOTA

J. E. Doran Fined.—A fine of $500 and payment of a license fee of $1,000 by John E. Doran of Minneapolis at Watertown recently followed Doran's plea of guilty to the charge of practicing medicine as an itinerant physician without having procured the special license required, according to a report of the state board of health. Doran's record in the files of the Bureau of Investigation of the American Medical Association is an unsavory one. In 1911, he is reported to have been arrested at Milbank, S. D., charged with practicing medicine without an itinerant license. A month later, it was reported that he was arrested in Grand Forks, N. D., and fined $50 for violation of the medical practice act of that state. In July, 1924, Doran's Colorado license is said to have been revoked after he had been found guilty of unprofessional and dishonorable conduct. Although Doran appealed the decision, the district court upheld the action of the state board. Doran appears to have associated with him other men of the same stripe and has operated under such names as "Progressive Doctors Specialists," "Associated Doctors" and "United Doctors."

TENNESSEE

Society News.—The seventy-second semiannual meeting of the Middle Tennessee Medical Association was addressed at Lawrenceburg, November 6-7, among others by Drs. John M. Lee, Nashville, on "Throat Infections in Infants and Children"; Paul G. Morrissey, Nashville, "Treatment of Gonorrheal Endocervicitis by Electrocoagulation"; Thomas J. Stockard, Lawrenceburg, "Differential Diagnosis of Thoracic Aneurysm and Mediastinal Tumors," and James C. Kelton, Murfreesboro, "Puerperal Septicemia of One Hundred Years Ago and Now, with Treatment." Dr. John H. Tilley, Lawrenceburg, was elected president of the association, succeeding Dr. Murray B. Davis, Nashville.

WASHINGTON

Society News.—The Spokane County Medical Society was addressed, October 9, by Drs. Alphonso N. Codd on "Obstructive Laryngeal Dyspnea"; M. M. Kalez, "Technic and Indications for Avertin Anesthesia," and John T. Bird, "Coronary Thrombosis."——"Cleft Lip and Palate" was the subject of an illustrated address by Dr. Herbert E. Coe, Seattle, before the Walla Walla Valley Medical Society, October 9, and "The Crippled Child" that of Dr. Alfred O. Adams, Spokane; Dr. Clyde W. Countryman, Spokane, reported a malignant tumor involving the heart and liver.

GENERAL

Medical Bills in Congress.—Representative Patman, Texas, was authorized by the House of Representatives, December 2, to file a minority report on H. R. 7884, a bill now pending in the House, with a favorable committee report, proposing to prohibit experiments on living dogs in the District of Columbia. S. 255, a bill for the promotion of the health and welfare of mothers and infants, was reached on the Senate calendar, December 3, but its consideration was prevented by objections by Senator Bingham, Connecticut, and Senator Phipps, Colorado. December 4, the Senate, on motion of Senator Jones, Washington, voted to proceed with the consideration of S. 255 and thereby made it the unfinished business of the Senate. H. R. 14059, introduced by Representative Rogers, Massachusetts, proposes to authorize an appropriation of $52,000,000 to provide additional hospital, domiciliary and outpatient dispensary facilities for persons entitled to hospitalization under the World War Veterans' Act.

Another Poses as Physician's Son.—During the week of October 25, Mr. S. Prentiss Baldwin, Cleveland, received a telephone call from a young man who reported an automobile accident in Lorain, Ohio. He said that he was the son of Dr. Frederick L. Hayes, Brookline, Mass., a Dartmouth classmate of Mr. Baldwin, that he was studying medicine in Minneapolis, and that a justice of the peace in Lorain had taken his money as a guarantee of his future appearance in connection with the accident. Mr. Baldwin gave him money for transportation from Cleveland to Boston. Investigation later proved that the story was false, and the chief of police of Lorain informed Dr. Hayes that no such accident took place there. This swindle is similar to that perpetrated at the expense of Dr. William Gerry Morgan, Washington, D. C., reported in The Journal, November 8. As Dr. Morgan was a classmate of Dr. Hayes and Mr. Baldwin at Dartmouth, it is believed that this is the same impostor and that he is working from a Dartmouth alumni catalogue.

Infant Mortality Decreased in 1929.—The U. S. Department of Commerce recently reported that the infant mortality rate showed a marked decrease as compared with 1915. The rate (68) was the second lowest since the establishment of the birth registration area in 1915. At that time this area was composed of ten states and the District of Columbia and included 31.1 per cent of the population of continental United States, while in 1929 there were forty-six states and the District of Columbia in this area, and 94.7 per cent of the total population of continental United States. For the sixth consecutive year, Oregon leads the states with the lowest infant mortality rate (48). In 1929, eleven states had lower rates than at any time since their admission to the registration area. These were: Minnesota, 51; Arkansas, 58; New Jersey, 60; Illinois, 61; Massachusetts, 62; Florida, 65; Michigan, 66; New Hampshire, 68; Louisiana, 74; Georgia, 76, and South Carolina, 91. Two states, Iowa and Maryland, in 1928 attained their lowest rates, which did not change in 1929. Taking the rate for the registration area of continental United States as a basis, twenty-four states had lower rates in 1929 and twenty-one had higher rates, while New Hampshire's rate was identical. With the exceptions of Colorado, Maine and Wyoming, the high infant mortality rates in these twenty-one states were due to the great infant mortality among Negro populations, especially in rural districts. The birth rate for the year 1929 was 18.9, the lowest for any year since the establishment of the birth registration area. Oregon had the lowest rate (14.1) of any state in the registration area.

Society News.—At the third annual meeting of the Central Society for Clinical Research in Chicago, November 21, Dr. Louis Leiter, Chicago, was elected president for the ensuing year, and Dr. Lawrence D. Thompson, St. Louis, secretary. The program included papers by Drs. William J. Dieckmann, St. Louis, "Focal Necrosis of the Liver"; Elmer L. Sevringhaus, Madison, Wis., "Study of Five Hundred Diabetic Patients"; John H. Foulger and Johnson McGuire, Cincinnati, "Intravenous Administration of Barium Chloride in Humans," and Isadore Pilot, Chicago, "Sporadic Septic Sore Throat Due to Streptococcus Epidemicus."——At the recent meeting of the American Association of School Physicians at Fort Worth, Texas, Dr. Sven R. Lokrantz, medical director of the Los Angeles city schools, was elected president; Dr. William A. Howe, Albany, was reelected secretary.——At the annual meeting of the American Public Health Association, October 30, Dr. Hugh S. Cumming, Washington, D. C., was installed as president, Dr. William C. Hassler, San Francisco, made president-elect, and Mr. Homer N. Calver, New York, reelected secretary. The next annual meeting will be held in Montreal, Quebec, September 14-17.——Dr. Alfred S. Giordano, South Bend, Ind., has been appointed, with others, a member of the advisory editorial board of the new *American Journal of Clinical Pathology*, to be published by the American Society of Clinical Pathologists. His name was inadvertently omitted from the list of members published in The Journal, November 1.——At the thirty-eighth annual meeting of the Association of Military Surgeons of the United States in September, Capt. James C. Pryor, medical corps, U. S. Navy, was elected president; Col. Charles R. Reynolds, medical corps, U. S. Army; Col. Charles W. Comfort, Jr., medical corps, Connecticut National Guard; Comdr. William S. Bainbridge, U. S. Naval Reserve, and Asst. Surg. Gen. Ralph C. Williams, U. S. Public Health Service, vice presidents, and Brig.-Gen. Jefferson R. Kean, U. S. Army, retired, secretary, reelected.

Foreign Letters

LONDON

(From Our Regular Correspondent)

Nov. 22, 1930.

Medicine and the State: Chief Health Officer's Apologia for Medical Socialism

At a public health conference held in London, Sir Arthur Newsholme, late principal medical officer of the local government board—now the ministry of health, gave an address on medicine and the state. He said that the public was constantly being reminded of the excessive expenditure on the social services, but on the medical side not a single service could be stopped without national injury. What was needed was critical examination of the extravagant and wasteful expenditure on these services. There were vices of incoordination, overlapping, hiatus. The defects of the national health insurance act were the absence of consultative, including pathologic, services, failure to provide hospital treatment, and the exclusion of the wife and dependents. He could not avoid "the burning question" of medical certification, which had involved the moral degradation of individual physicians who had certified without thorough examination and without realizing their responsibility not to certify merely to please the patient. Such cases, he was confident, were exceptional, but borderline cases were numerous and in such the physician gave his patient the benefit of the doubt. His wish to retain his patient, who could leave him, had some weight. How could this sinister association of medicine and money be avoided, or, if inevitable, how could the weakness of a physician desirous of pleasing his patient, and the unscrupulous or unthinking desire of the patient to have a rest from work, even when not incapacitated, be counteracted? Some common incapacitating conditions had no objective signs. So-called chronic rheumatism was a common source of overcertification. Neither physician nor patient might in this case be to blame. How could the stream of excessive claims be checked? The former lodge mental attitude in which pride was taken in not "going on the club" had disappeared. The democratic management of each society had almost ceased and more than 60 per cent of the insured belonged to centralized societies, in the working of which they could take practically no part. He advocated giving a graduated bonus to every one reaching 65 whose sickness claims had been below the average. There was much to be said for making the patient pay a portion of the charge for the drugs prescribed. Often the drugs were unnecessary and had been ordered to satisfy the patient. He doubted whether an effective remedy was possible for overcertification unless the insurance societies were regionalized and placed under local management.

These admissions of a man who until recently was the chief health officer of the country, and chief administrator and supervisor of the medical working of the insurance act, are noteworthy. A supporter of the medical socialism of the act, he endeavors to defend it but has to admit that the two great evils of overcertification of illness and overprescribing of drugs are unavoidable. The old lodge system, with which his comparison is so disparaging, could check malingering simply because it was not socialistic. The members felt their responsibility not to make unnecessary claims on their own funds or enforced this on one another when necessary. Now the funds come mainly from the state or the employer and are regarded as a cow to be milked.

Readmission of Women Students to a London Hospital

During the war the scarcity of men students led to the admission of women to London medical schools, which had always been restricted to men. In 1928 an opposite movement occurred and women were again excluded from these schools. The reasons given were that the men students objected and that teachers had complained of difficulty in teaching certain subjects to mixed classes. For some unknown reason, similar difficulties with regard to women students never arose in the provincial medical schools. The *British Medical Journal* has recently stated in its educational number that the ban on women in the London medical schools can be only temporary. This view has quickly been confirmed. King's College Hospital has decided to readmit women students in limited numbers. The authorities state that the exclusion in 1928 was simply a protective measure, because it was feared that the closing of other hospitals to women might result in an undue invasion of King's College Hospital and that therefore the step was only temporary and experimental. The objections to coeducation urged in other hospitals, such as embarrassment in the teaching of certain subjects to mixed classes or distraction of men students, have not been experienced at King's College. The only other London hospital where coeducation now goes on is University College, which admits not more than twelve women students annually, so that about forty women are studying there at one time. There is also the Royal Free Hospital (London School of Medicine for Women), which admits only women students. Some of the great London schools, such as Guy's and St. Bartholomew's hospitals, have never admitted women students at any time.

The Physician Who Described Acromegaly in Himself

An account has been given of Dr. Leonard Portal Mark (The Journal, October 11, p. 1109), the physician who recently died after living—it is noteworthy—a vigorous life to the age of 75, though suffering from acromegaly for more than thirty years, and turning his misfortune to account by minutely describing the course of the disease in himself. In Dr. Mark's book and in his case, Dr. Harvey Cushing, when visiting London for the International Medical Congress in 1913, took a great interest. Dr. Mark desired that when he died a necropsy should be made at his medical school, St. Bartholomew's Hospital, in order that further light might be thrown on the pathology of the disease. This has been done by Dr. E. R. Cullinan. The changes of acromegaly were found to a moderate degree. The vault of the skull was enlarged (25 inches in circumference) and the inner and outer tables were greatly thickened (in parts 1 inch). The pituitary fossa was somewhat enlarged and its posterior wall softened. The mandible was larger and thicker than normal. The radius and ulna were enlarged and the hands typically acromegalic. The pituitary was slightly larger than normal and of soft consistency. The thyroid was enlarged. Advanced atheroma (with thrombosis of the common iliac and right popliteal arteries) and chronic interstitial nephritis of the arteriosclerotic type were also found. So much for the gross changes. A detailed study is to be made of certain valuable material, which has been retained, at Dr. Mark's own request.

The Danger of Medicine Producing Racial Degeneration

At the annual dinner of the Royal Society of Medicine, Dr. Barnes, F.R.S., Bishop of Birmingham, who is an eminent mathematician and has been described as a liaison officer between science and religion, discussed the possible dysgenic effect of medicine in producing racial degeneration. There might come a time when biochemistry would enable medicine to give an immunity to ill health such as had been enjoyed only by exceptional individuals in the past. In the modern world, in spite of political, social and moral disorder, it was good to be alive. Never since the golden age of Greece had mental energy been more fertile. But what probability was there that the present great era of scientific progress would come to an end—that the Dark Ages would again come over Europe? Medical skill and public hygiene would ultimately be disastrous if they preserved inheritable mental or physical defects. It was now known that dysgenic mutations could occur alike in plants and in animals, as it were spontaneously. Having appeared, they could be inherited and, unless eliminated by a hostile environment, they remained a permanent menace. Now medical science destroyed the power of hostile environment but left inheritable characters untouched. Mental defect was a dysgenic mutation which was a grave menace to social welfare. Mental defectives already numbered nearly 1 per cent of the community, and the families in which the defect was latent made up inferior racial stocks amounting to some 10 per cent of the community. What would happen to humanity during the relatively inexhaustible future? Would medicine conquer disease and would our descendants, perfect in body and more powerful in brain, create Utopia? Or would the age of the mammals, which had endured for some 60 million years, pass away? The great reptiles had vanished. If man passed from this globe, would some new form of life, higher in the evolutionary scale, in due course lord it over the earth? He could ask such question without anxiety and receive any answer without dismay, for he was certain that man's permanent habitation was not on the earth and that his spiritual achievements were imperishable.

Invention to Prevent Loss of Life in Automobile Accidents

A device which, it is claimed, will prevent deaths from automobile accidents, has been tried out by the Institute of Patentees. It consists of a grooved roller, about 6 inches in diameter, attached to the front of automobiles. Its action prevents a person knocked down from being crushed under the wheels. The roller revolves in a direction opposite to that of the wheels of the car and pushes any obstruction on the road, such as the body of a man, along with it. The invention is the work of a London physician, Dr. Vernon Clifford. Hospital experience showed him that knocking people down and breaking bones did not kill them, but that the great loss of life was due to crushing beneath the wheels of the car. He made experiments by attaching the wheel of a lawn mower to the front wheel hub of a bicycle and getting the mower wheel to revolve in the opposite direction to that of the bicycle wheel. He rode it round the lawn, pushing a cigaret case and tobacco pouch and pipe in front of it, and found that he could not run over them. He then made a toy model with which he tried to run over dolls on a table. For the final test the attachment was fixed to a heavy commercial lorry and at a low speed a man was rolled along the ground for a distance of 20 feet. He was not injured. A dummy was then thrown in front of the vehicle while traveling at from 15 to 18 miles an hour. It was simply rolled along in front of the lorry. Under mass production Dr. Clifford estimates that the attachment would cost $50 and that its general use would save 4,000 lives annually in this country.

Doubly Injured by Automobiles

A shocking double injury by automobiles in southeast London shows the terrible danger now of our streets. An inquest was held on a schoolmistress, aged 42, who was run down by a motorcycle and while lying on the ground and being treated for injuries was again run into by an automobile. She was removed to a hospital, where she died. The result was that a captain of artillery, who had been arrested on a charge of being drunk while in charge of an automobile, was further charged with manslaughter.

The Most Complete Dental Clinic for Children

At the opening of the new Eastman Dental Clinic of the Royal Free Hospital, erected, equipped and endorsed by Mr. George Eastman of Rochester, N. Y., General Dawes, American ambassador, described it as the most complete and most modern children's dental clinic yet erected. Mr. Eastman had long been interested in the dental treatment of the coming generation and had selected London as an ideal place for another demonstration of the value of preventive treatment. He was establishing another in Rome and still another in Stockholm. There was also every possibility that one would be established in Paris. Dr. Burkhart, who is in charge of the Eastman clinic at Rochester, N. Y., also took part in the proceedings.

PARIS

(From Our Regular Correspondent)

Nov. 12, 1930.

The Thirtieth Congress of Urology

The thirtieth annual session of the Société d'urologie has just closed. It was presided over by Dr. Chevassu, surgeon to the Hôpitaux de Paris and agrégé professor at the Faculty of Medicine. It was attended by a large number of urologists, a considerable proportion of whom were foreigners. Prof. Maurice Gérard of Lille, who presented a paper on "Contusions of the Kidney and Their Remote Results," gave a good clinical description of the condition and expounded various theories advanced to explain the mechanism of renal contusion (compression exerted by the vertebrae, hydraulic pressure of the kidney fluids, traction exerted by the pedicle) but did not give his personal approval to any one of them. The immediate prognosis is often favorable, but the remote results are uncertain, as partial or total atrophy of the organ may ensue, owing to retraction of the cicatrix. In the majority of cases, however, the cure may be complete, and the functioning of the kidney may become entirely normal. The newest feature of the paper was the study on the judicial aspects of the condition and the percentage of compensation claimable in contusions resulting from an accident. The decision will be based on the functional value of the injured kidney. If nephrectomy has to be performed, the proportion of disablement should be placed at 50 per cent. In the discussion that followed, Professor Legueu held that traumatic nephritis does not exist but that it sometimes becomes necessary to combat traumatic hydronephrosis, which is a genuine entity of mechanical origin. Mr. Lepoutre of Lille spoke on tardy ecchymoses, the sign of unrecognized hematomas, complications caused by a previously existing hydronephrosis and by the lithiasis that may appear tardily. Mr. Duvergey of Bordeaux referred to the danger of later infection in a contused kidney, chiefly by *Bacillus coli.* Mr. Pasteau spoke on traumatic hydronephrosis. Among the nonofficial communications read by their authors were: "Peculiarities of Epidural Anesthesia," Dr. Phélip; "Result of Phenolization of the Cord (Doppler Operation) in the Impotent"; "Prostatitis of Dental Origin," Dr. Duvergey; "Vaccinotherapy in Renal Tuberculosis," Dr. Gayet of Lyons. Several speakers emphasized the dangers of cystostomy at the first onset, by reason of the too sudden changes brought about in the excretory functions of the kidney. Mr. Chauvin of Marseilles has found that all danger can be eliminated by applying a ureteral retention sound several days before performing the cystostomy. Examination by the use of intravenous injections of sodium 2-oxo-5-iodo-pyridine-N-acetate was the subject of communications presented by Chevassu of Paris, Blanchet of Bordeaux, Lepoutre of Lille, Boeckel of Strasbourg, Bonnet of Nice, Perrier, Pasteau and others, all of whom declared that they were well satisfied with the method. Mr. Teposu of Bucharest reported, however, a case in which an attack of tetany was brought on that lasted ten minutes. M. R. Darget of Bordeaux employed pyelography to advantage by the insufflation of air into the pelvis. Renal tuberculosis and vaccine treatment were discussed in several communications.

The general assembly of the Association d'urologie, which convened after the congress, awarded, for the first time, the prize of the association amounting to 20,000 francs ($800), the recipient being Dr. Chabanier, for many years head of the laboratory at the Hôpital Necker in Paris. This prize is made up by gifts from 184 foreign members in fourteen different countries. The Tuesch prize (7,500 francs, or $300), established by a grateful patient treated by Dr. Chevassu and destined for a young French investigator under 30 years of age to encourage him in his work, was awarded to Dr. Jacques Delarue, although he is not a urologist but is carrying on anatomopathologic studies on the tuberculous focus.

The French Congress of Orthopedics

The twelfth French Congress of Orthopedics met recently under the chairmanship of Agrégé Professor Albert Mouchet. The two main topics on the program were: (1) Coxa Vara in Adolescence, with a paper by Mr. Georges Huc of Paris, and (2) Obstetric Paralysis of the Upper Limb, presented by Mr. André Rendu of Lyons. Huc, who ascribed to coxa vara multiple and diverse origins, recommended as treatment prolonged extension in abduction and inner rotation, or the application of the Whitman apparatus at an early stage, followed later by a subtrochanteric osteotomy, with the use of a plaster cast for two months. Forced adjustment or refracture gives only bad results and is almost certain to lead to arthritis. This paper was subjected to criticism, notably by Albert Mouchet and Roederer. They preferred the Whitman apparatus to prolonged extension and advised immobilization in a plaster cast for a much longer period. In the opinion of many speakers, the prognosis of coxa vara remains grave, and simultaneous treatment of the general condition is important. In discussing the second topic, Rendu gave a complete survey of paralysis of the arm of obstetric origin in the new-born, which usually finds its explanation in undue traction applied to the brachial plexus. He advises first massage; then the application of an apparatus that will maintain the arm in abduction at 90 degrees and in inner rotation. He reviewed the various treatments proposed and pointed out the good effects of osteotomy applied to the humerus in order to adjust the axis of the limb. Dr. Mencière of Reims, who was present at the session, claimed priority for this operation, which he began to use in 1902. Mouchet emphasized the good results that the operation produces.

Epidemic in Marseilles Due to Ticks

A peculiar epidemic appeared in Marseilles, two years ago, and has been again reported at present. It was an unknown disease resembling exanthematic typhus but yet frankly different from that and, moreover, mild in its course. The researches made to elucidate the question remained fruitless, and the Academy of Medicine when consulted was unable to find a plausible explanation. Mr. Brumpt, professor at the Faculté de médecine in Paris, has recently found the solution of the enigma, and has explained his views in a communication addressed to the Academy of Sciences. He diagnoses the malady as the *fièvre boutonneuse* of Africa, transported to Marseilles, which is in constant relations with the ports of northern Africa, by ticks. Brumpt has succeeded in transmitting the Marseilles exanthematous fever to man through the intermediation of adult ticks obtained in the form of nymphs from dogs in Marseilles. The experiment, which proves the great resistance of the virus in these animals, shows also the identity of the *fièvre boutonneuse* of Africa and the exanthematous fever of Marseilles. The author recommends, as prophylaxis, bathing of the dogs in an arsenical solution and the encouragement in Marseilles of a small insect of the *Ixodiphagus* genus, which is a great destroyer of ticks.

Celebration in Memory of Professor Laveran

The memory of Professor Laveran, who discovered the hematozoon of malaria, and to whom a monument was unveiled last spring at Constantine during the ceremonies commemorating the centenary of the conquest of Algeria, has again been honored at Paris by commemorative ceremonies held at the military hospital of the Ecole du Val-de-Grâce, where he was professor until he reached the army age for retirement, after which he was director of a laboratory at the Institut Pasteur until his death. The ceremonies were held in the Great Hall of the school. Dr. Roux, director of the Institut Pasteur, presided. Professor Sieur, president of the alumni association of the Ecole de santé militaire du Val-de-Grâce, expressed the thanks of the association to those who had subscribed to the monument. Mr. Calmette gave an account of the life of Laveran and of his discovery. Addresses were delivered by Troussaint, a former co-worker of Laveran; by Marchoux, and by Rouvillois, the director of the school. An historical niche was established in the school, in which a glass case encloses the microscope and the observation records of Laveran. Then the audience proceeded to a spot in front of the entrance to the school, which will bear henceforth the name of "Place du docteur Laveran." A commemorative tablet was affixed to the house in which Laveran lived.

The League for Combating Venereal Disease

The *Ligue nationale française contre le péril vénérien* was established in May, 1923, after the session of the international congress of social hygiene and prophylactic education. The two presidents thus far have been Dr. Jeanselme and Dr. Queyrat. Its administrative council is composed of eminent representatives of the faculties of medicine, the faculties of military medicine, and of the Catholic, Protestant and Jewish churches. The league is functioning with great energy. Its activities take the form of lectures, theatrical plays, lantern slides, motion pictures, tracts and posters. Its publicity campaign is directed chiefly toward the teachers, in the hope that they will properly train the educators of the future. In 1928, 200 lectures were held, which were attended by 150,000 persons, 20,000 of whom were future educators. More than 100 films have been projected in 600 motion picture houses, before two million spectators. Small manuals have been prepared, in an ingenious manner, by the teachers of science and literature. Three significant and well executed posters have been distributed throughout France. A large number of special dispensaries have been opened. A special form of publicity has been carried out in the public urinals and comfort stations, a complete list of the public dispensaries being posted, accompanied by a few words of advice and instruction. A serologic institute has been created in Paris. At present it is located at the Faculté de médecine, but a special building to house it is being erected. The league was financed at first by private subscriptions. Then, gradually, government aid was given. The minister of public health makes the league an annual grant of 250,000 francs. At present, its annual resources amount to 1,500,000 francs ($60,000). It is far from possessing the financial resources of the prophylactic institute of Brazil, to which the Gaffrée-Guinle Foundation has given 90,000,000 francs ($3,600,000).

BUENOS AIRES

(From Our Regular Correspondent)

Sept. 30, 1930.

The Hypophysis and Diabetes

Dr. B. A. Houssay lectured recently at Montevideo, Uruguay, on the hypophysis and diabetes. He discussed his studies on experimental diabetes made in collaboration with Dr. Biasotti. While pancreatic diabetes in dogs is not modified by the removal either of the thyroid gland or of the medulla of the suprarenals, it is attenuated in intensity and its evolution is prolonged by removal of the hypophysis. Glycosuria and even diabetes is frequently associated with acromegaly. The association of diabetes with a thalamencephalic lesion is rare. Animals deprived of the hypophysis are very sensitive to the action of insulin. Dogs deprived of both the hypophysis and the pancreas may survive with a glycemia even during six months. In dogs with a lesion deeply localized in the tuber cinereum, diabetes has an evolution of the same intensity as that observed in control dogs deprived of the pancreas alone. These facts suggest that the hypophysis is an important factor in carbohydrate metabolism. It has been proved that the anterior lobe of the hypophysis has an action on the maturation and luteinization of ovarian follicles, on the acceleration of growth, on the thyroid gland, and on the cortex of the suprarenals. As a plausible hypothesis it is believed that acromegalic diabetes may be due to a hyperfunctioning of the anterior lobe of the hypophysis.

Congress of Surgery

The second National Congress of Surgery was held at Buenos Aires, Argentina, with Dr. E. Belaustegui as president. The official speakers were Drs. R. Solé, who spoke on surgery in gastric ulcer; P. Chutro, on postoperative complications of appendicitis; R. Pasman and A. Rodríguez Egaña, present status of the surgical treatment of Pott's disease, and J. C. Ahumada and A. Caviglia, surgical treatment of cancer of the breast. The congress was a success. There were operative demonstrations in the mornings, and expositions of national products and instruments made in Argentina and also film projections, in the afternoons.

New Government Hospitals

The national government of Argentina finished the construction of hospitals at Añatuya and Frías, as well as several small branches or first aid posts at Ojo de Agua and Fernández, in the province of Santiago del Estero. Both the hospitals and the first aid posts are complete and well constructed. In the province of Santiago del Estero, trachoma and malaria have spread extensively.

Foreign Guests in Argentina

Drs. T. Martins and Barros Barreto, both of Rio de Janeiro, delivered lectures at Buenos Aires on the testicular hormone and the prophylaxis of yellow fever, respectively.

Prof. E. Leschke of Berlin lectured before the Asociación Médica Argentina on clinical and physiologic aspects of the sympathetic nervous system.

Prof. G. Marinesco of Bucharest delivered several lectures on neurology at Buenos Aires, Rosario and Córdoba, and gave laboratory demonstrations.

Scholarships for Graduate Work

The National University of Buenos Aires established scholarships for graduate work in several branches of science, eight of which have been given to Argentine physicians. The Rockefeller Foundation gave a scholarship for studies of physiology in Cleveland to Dr. O. Orías. Scholarships will be also given in Argentina by the Guggenheim Foundation.

Prizes Awarded

Dr. M. Royer obtained the prize which during the year 1929 was assigned for the best thesis of medicine. His thesis dealt with the normal and the pathologic physiology of urobilin.

Dr. A. Gutierrez obtained the prize which during the year from 1928 to 1929 was assigned for the best medical paper. His article dealt with the surgical anatomy of the peritoneum.

Dr. A. Battro obtained the Luis Guemes prize, for his clinical and experimental studies on occlusion of the coronary arteries.

Dr. Espejo Solá obtained the E. Wilde prize, for his studies on the hygiene of schools.

A New Review of Medicine and Surgery

The medical and scientific productions of the Latin-American countries are not well known in the countries of Europe and North America owing to the difficulties of language and, more particularly, by reason of the limited circulation of the Latin-American reviews. To the latter factor may be ascribed the fact that also the mutual knowledge between the Latin-American countries is very slight, it being common for the works and the activities of a South American author to be better known in countries of other continents than in the other countries of South America. The publishing house of Masson & Cie, Paris, has begun in Paris the publication of the *Revue Sud-Américaine de Médecine et de Chirurgie*, a French review, under the management of Joao Coelho, which will contain South American scientific articles. The review will comprise original articles, a current literature department and accounts of medical society meetings. The extensive connections of this publishing house throughout the world will assure a wide distribution of the review in all countries.

Trichina in Pigs in the Dutch East Indies

Trichinosis, as a disease, is unknown in the Dutch East Indies, though it is not impossible that a case may occur now and then. As far as known, there is no regular search made for *Trichina* in connection with the control of food products. Nevertheless, in order to be on guard, from time to time a sample of meat is taken, for examination, from animals killed at the abattoir in Medan, Sumatra East Coast. It has been found that parasites are discovered in every sixty-third animal examined. A little later, daily examinations were made and it was found that the cases were not so rare as supposed. Thus far, 901 pigs have been examined, 830 of which were from China and 68 from Batac, while 3 were wild boars. There were nine animals from Batac affected with the disease. Those from China were not affected. After the discovery of the ninth case of *Trichina* in the pigs from Batac, no more supplies from there were bought. The finding of parasites is important from the standpoint of compulsory control of the food products offered for sale in a community. Under the present circumstances, with human beings, dogs, pigs and rats living in such close proximity, the conditions are too favorable for the propagation of the disease. The dissemination can best be checked by prohibiting the exportation of animals from infected regions.

The Crusade Against Tuberculosis

The *Verslagen en Mededeelingen betreffende de Volksgezondheid* publishes statistics on the mortality from the various forms of tuberculosis. The adjoining tabulation shows the mortality for 10,000 of population.

Year	Pulmonary Tuberculosis	Cerebral Tuberculosis	Other Forms	All Forms
1924	7.91	1.43	1.28	10.68
1925	7.01	1.29	1.56	9.86
1926	7.22	1.13	1.33	9.68
1927	7.07	1.09	1.31	9.49
1928	6.16	1.98	1.27	8.42
1929	6.42	0.96	1.23	8.61

The organization of consultation centers has made progress, and the number of visits on the part of patients is steadily increasing. The number of new patients registered for the first time, during the years 1924 to 1929, was as follows: 1924, 16,572; 1925, 22,426; 1926, 24,340; 1927, 25,522; 1928, 26,251, and 1929, 28,722.

Dengue and Yellow Fever

The relationship between dengue and yellow fever has already attracted attention. Snijders, in the *Nederlandsch Tydschrift voor Geneeskunde*, publishes the results of his study on the subject. The clinical picture of mild cases of yellow fever closely resembles that of dengue; the transmitting agent for both diseases is *Aedes aegypti*; in both diseases the insect can become infected only during the first three days of the disease, and th "extrinsic incubation" covers a period of from nine to twelve days. Recently, Stefanopoulo, endeavoring to verify the researches of Blanc and his collaborators in Greece, showed that convalescents' serum of dengue has no effect on the virus of yellow fever. Attempts to infect rhesus monkeys with the virulent blood of dengue patients proved unavailing. No *immunization* phenomena toward yellow fever followed the *inoculation.* It is evident that dengue and yellow fever are not *one and the same disease.* Snijders emphasizes, however, their close relationship. Furthermore, it should be borne in mind that the term "dengue" is collective and covers a group of diseases. It is quite possible that other forms belonging to this group are immunologically nearer to yellow fever than is the form observed in Greece. Bonne referred to this possibility in connection with a disease similar to dengue, which he studied, in 1923, in Dutch Guiana.

Malaria in Dutch East Indies

Dr. W. De Vogel, member of the permanent committee on public health, gave recently a survey of conditions in the Dutch East Indies as regards malaria, and called attention to the fact that, contrary to the observations in certain countries of Europe, the urban mortality is much higher than that of the rural districts. The conditions are similar, therefore, to those that prevail in the United States. He confined his studies more particularly to the island of Java. The rural population here is so preponderant that the high urban mortality passes unnoticed in the figures of the average mortality of the entire population. The combined mortality of the rural districts and the cities, during the period 1912 to 1923, was 20 per thousand of population annually. If this figure is compared with the average mortality rate during the same period in the three principal cities of Java—namely, Batavia, Semarang and Surabaya—seaports on the northern coast of the island, one finds the exceedingly high averages of 46.8 per thousand for Batavia, 55.25 per thousand for Semarang and 55.06 per thousand for Surabaya. These figures have stimulated the public health service, during the past several years, to institute a persevering search to discover the causes of this situation, in order to combat them in an effective manner. Its efforts have not been in vain. The average annual mortality in the three cities mentioned has been lowered, during the period 1924 to 1929, to 39 per thousand for Batavia, 31 per thousand for Semarang and 29 per thousand for Surabaya. But if, for the cited period of five years, the annual mortality of the entire population of Java is compared with the average annual mortality of the urban population, there are obviously many difficulties to be surmounted before a situation comparable to that of the Netherlands can be attained.

Postvaccinal Encephalitis

In the 1929 report of the society for the promotion of antismallpox vaccination, in Rotterdam, the secretary announced that in the Netherlands most children are vaccinated between the second and the fourth year (and of these the majority between the third and the fourth year). Corresponding to this more advanced age for vaccination, the Netherlands has a higher percentage of postvaccinal encephalitis than other countries. The following figures deserve to be compared: the Netherlands, one case of encephalitis for each 4,000 first vaccinations; England, one case of encephalitis for each 48,000 first vaccinations, and Germany, one case of encephalitis for each 750,000 first vaccinations.

Immigration to the East Indies

The total immigration of all classes of population to the Dutch East Indies diminished, in 1929, 10 per cent as against the figures for 1928, the total having been about 6,000. This diminution was due exclusively to the decline in emigration from China.

BERLIN

(From Our Regular Correspondent)

Nov. 17, 1930.

A Health Record Book

In the decade preceding the war, the life expectancy of every German was 50 years; according to mortality statistics based on the census of 1925 the present life expectancy is 56 years, in spite of the crowding of the population into inadequate dwellings and the vast number of unemployed. Professor Grotjahn, social hygienist at the University of Berlin, brought out recently at a meeting that this pleasing development in public health is due in part to progress made in the sociohygienic welfare work of the communal administrations. But the development of the welfare system is not yet complete. The most important data on the various welfare cases, which today are scattered about in the files of the welfare centers, should be collected at a central bureau. In 1891, W. Schallmayer published an article in which he demanded the introduction of what he termed a *krankenpass,* or health record book, to be required to be carried by every citizen of the *reich* and to be deposited at certain stated times at a central bureau, to serve as sources of information in definite cases. Such a record book would not only be valuable to the individual in questions involving marriage and evidence of hereditary weaknesses, for example, but would furnish also an excellent basis for statistics on chronic disease, which today are occupying the attention of hygiene to an increasing extent. Not only statistical facts pertaining to birth, marriage and death should be reported to the registrar's office but also the most important illnesses or disorders, accidents and physical data in general, where they should be recorded in individual record books, to which not only the subject himself but also the authorities should have access under exactly defined legal conditions, for their own information or in connection with welfare, legal and insurance matters, including determination of disablement in compensation claims.

The Housing Situation

The housing problem, which is the most important hygienic problem of today, has received a certain clarification from the figures of the federal census, which have just been published in a two-volume work and offer for the first time since the war a comprehensive survey of housing conditions. On the basis of this rich material, Prof. E. Friedberger, the director of the Forschungsinstitut für Hygiene in Dahlem, near Berlin, gives in an article in the *Deutsche medizinische Wochenschrift* a characterization of the housing situation in Germany and opens ways for combating it. From the statistics it appears that, in 1927, there were in the German *reich,* exclusive of the Saar region, 1,150,000 persons who were seeking suitable dwellings, 560,000 of whom had no independent dwelling whatever. The majority of the buildings used for residential purposes are small houses; but the majority of the dwellings are found in large or in moderate-sized buildings. The number of large buildings occupied for residential purposes increases with the size of the commune or city. In the small towns, more than 40 per cent of the dwellings consist of one or two family houses, while in the large cities scarcely 10 per cent are of that class. Of the houses erected since 1918, about half are designed for one family only; but the influence of that change in style of construction on the general nature of the residential buildings as a whole is scarcely recognizable. One fifth of all the one-family houses date from the postwar period. More than nine tenths of the dwellings consist of small apartments (one to three rooms) and moderate sized apartments (four to six rooms).

An index of the bad housing situation can be obtained from the average number of persons to each living room. In the German cities more than three million persons live in overcrowded dwellings. The average number of persons to an occupied dwelling is 3.8; 79 per cent of dwellings have an average of two persons to each living room, and 5.6 per cent of all dwellings in communes with more than 5,000 inhabitants (affecting a total of 3,200,000 persons) are overcrowded. Almost 10 per cent of the urban population lives, therefore, in dwellings in which there are more than two persons to each living room. Another significant index of the housing situation at present is the increase in the number of subtenants since the war, the number being seven times as great as formerly. At present the number of subtenants equals the number of tenants at first hand. In the smaller towns, 6 per cent, and in the larger cities, 10 per cent, of all dwellings have subtenants. The dearth of reasonably priced dwellings affects, of course, more particularly the families with a large number of children (four or more, unmarried). The number of persons per living room in such families is almost twice as great as in the smaller families. In the sixteen largest cities, there are about four persons to a dwelling; but in the families with four or more children the average number is seven. The bad housing situation of recent years is due partly to the interruption of building activities and partly to the unusual increase in the number of households resulting from the fact that the number of persons more than 15 years old has increased, of late, 21.3 per cent, whereas the number under 15 years of age has increased only 17.9 per cent. The marriage rate is high, with the result that the number of households has increased 19.5 per cent in recent years. It is the author's opinion that the type of residence that will ease the situation most rapidly is not the one-family dwelling but the large apartment house constructed in accordance with hygienic principles. It is true that the private home with its own yard, located in the outskirts of the city, is preferable, from the hygienic point of view, to the dwelling in the massive apartment house, even though it may differ materially from the old type of tenement house. But the expense is too great, and therefore the idea of the one-family dwelling is being abandoned. Thus, in 1928, the number of new one-family dwellings in the large cities was reduced 50 per cent. The large apartment house is the only solution that is practicable. The buildings should be so constructed that the residential units can be easily enlarged or made smaller to meet changing conditions in the families occupying them. If children are born, it should be possible to secure additional adjoining rooms, given up perchance by a family whose children have grown up and left the apartment; or, if that is not always feasible, a larger or a smaller apartment should be available in the same building. The apartment house affords persons of moderate means an opportunity of securing the advantages of such mechanized equipment as a central heating plant, bathrooms, laundries and modern cooking facilties, which otherwise only occupants of luxurious dwellings can enjoy, whereas they are especially important for persons of moderate means because of the time saved, and, in addition, they have a high hygienic value.

The Use of Aluminum Vessels for Cooking

On account of persistent assertions that the use of aluminum vessels for cooking is injurious to health because the cooking processes cause small particles of the metal to become disintegrated, the federal bureau of health instituted a thorough inquiry. After many experiments on animals, extending over months, and also observations on man with comparatively large doses of aluminum (much larger than would be involved in abrasions from cooking vessels), no manner of disturbances could be noted, and it was found that the metal contained in the ingested metal compound does not enter the body fluids from the intestine but is carried off through the gastro-intestinal tract. Neither in the blood, the urine nor in the organs and tissues of dogs allowed to ingest, during a year's experimentation, significant doses of aluminum could more aluminum than usual be found. Nor could any injuries to health or even disturbances of well being be observed in man. Thus the opinion of the bureau, rendered in 1893, is confirmed—that household and kitchen vessels of aluminum can be employed with perfect safety.

Clinic for Jaw Surgery

In the Charité Hospital in Berlin, a clinical center for the surgical department of the Zahnärztliches Institut has been established on the first and second floors of the preserved north wing of the old Charité building. The clinic is under the direction of Professor Axhausen, who was for many years a pupil of Professor Hildebrandt. With the creation of this new clinic, modern surgery of the jaws has now been officially recognized as a part of dental surgery. The range of activity of the Kieferklinik is easily delimited. In addition to the severe types of disease that have their origin in the dental apparatus, all pathologic conditions are included that require for their treatment a combination of surgical and dental procedures.

Physicians Who Are Total Abstainers

Der Verein abstinenter Aerzte des deutschen Sprachgebietes (association of physicians of German-speaking countries who are total abstainers from alcoholic beverages) met, September 2, under the direction of its chairman, Geheimrat Abderhalden of Halle, in the auditorium of the Deutsches Hygiene-Museum in Dresden. The society has increased its membership in Germany in recent years, but the number is by no means equal to the percentage of members in some other countries, such as Austria and Switzerland, which have, on a percentage basis, ten times as many total abstainers as Germany. The society has never advocated prohibition. The society, however, regards it as fitting that men and women who demonstrate the manifold injuries caused by alcohol and are desirous of combating them should apply their deductions to their own persons. At the scientific session, Ministerialrat Thiele of Dresden spoke on "Industrial Hygiene and Alcohol," Senator Dr. Holitscher of Komotau on "Alcohol and Health," and Abderhalden on the aims of the association. Scientific bases for combating alcohol in an unequivocal manner must be supplied, and by lessening the expenditures for alcohol the means should be secured for a type of physical and mental culture that will exclude alcohol as far as it is possible.

The Antialcohol Society

At the annual meeting of the Deutscher Verein gegen den Alcoholismus the main topics discussed were: Traffic Accidents Due to Alcohol. Their Prevention and the Determination of Penalties; Welfare Aid to Alcohol Addicts; Legal Protection for the Children of Alcohol Addicts; Treatment of Alcohol Addicts (Open or Closed Type of Sanatorium). Without the cooperation of the psychiatrist, whose duty it is to study the various types of alcohol addicts from the hereditary, biologic point of view and from the standpoint of individual psychology, there is no consistent treatment and cure of addicts. Especially in regions in which strong brandy is indulged in to excess, severe damage to health becomes manifest. Professor Burgers of Königsberg called attention to the fact that drinking to excess is particularly noticeable in connection with epidemics, with the result that the mortality is still further increased.

Prize for Paper on Diseases of Metabolism

The Gesellschaft fur Verdauungs- und Stoffwechselkrankheiten, at its tenth general assembly, offered (for the coming year only) a "Boas prize" amounting to 1,000 marks, or $238. The topic selected for the prize offering is "The Bacterial and the Abacterial Genesis of Disorders of the Pancreas." Competing papers must be turned in by April 1, 1931. Further details may be secured from Prof. R. von den Velden, general secretariat, Berlin W 30, Bambergerstr. 49.

Marriages

Cavins R. Marshall, Indianapolis, to Miss Margaret E. Jones of Gas City, Ind., November 22.

George E. Nesche, Oakland, Calif., to Miss Marjorie Ayers of Lodi, Calif., October 2.

Gilbert L. A. Dailey to Miss Mary Helen Geiser, both of Harrisburg, Pa., October 30.

James F. Balch, Jr., to Miss Margaret Lenora Guthrie, both of Indianapolis, October 9.

Karl W. Doege, Marshfield, Wis., to Miss Elizabeth Meyeroff, in Germany, recently.

George J. Searle, Jr., Mansfield, Ohio, to Miss Mary Brown, November 19.

Arthur V. Cole, Hammond, Ind., to Miss Roberta Gardner in October.

Clarence J. Buckley, Cleveland, to Miss Marian Smith, October 29.

Deaths

Robert Wilkinson Johnson, Baltimore; University of Pennsylvania School of Medicine, Philadelphia, 1879; member and past president of the Medical and Chirurgical Faculty of Maryland; member of the American Orthopedic Association and the American Surgical Association; formerly professor of principles and practice of surgery, Baltimore Medical College; at one time on the staffs of the Maryland General Hospital and the Church Home and Infirmary; aged 76; died, November 13, of carcinoma of the liver and myocarditis.

William Elisha Lawson, Jr., Albany, N. Y.; University College of Medicine, Richmond, Va., 1911; member of the Medical Society of the State of New York; associate in medicine, Albany Medical College; associate physician to the Metropolitan Sanatorium, Mount McGregor, 1913-1920; medical director of the Albany Hospital Tuberculosis Sanatorium; aged 43; died, November 15, in the Saranac Lake (N. Y.) General Hospital, of spontaneous subarachnoid hemorrhage.

Henry Alexander Macgruer, Syracuse, N. Y.; Columbia University College of Physicians and Surgeons, New York, 1898; professor of diseases of the skin and syphilis, Syracuse University College of Medicine; served during the World War; at one time city health commissioner; formerly on the staff of St. Mary's Maternity and Infant Hospital; aged 56; died, November 15, of portal cirrhosis of the liver and cholemic edema of the lungs.

Harry Neal Kerns, Livermore, Calif.; University of Michigan Medical School, Ann Arbor, 1912; member of the American Psychiatric Association; at one time assistant clinical professor of mental hygiene and psychiatry, Yale University School of Medicine, New Haven; formerly a major in the Medical Corps, U. S. Army; on the staff of U. S. Veterans' Hospital number 102; aged 43; died, November 10.

Cyrus Thompson, Jacksonville, N. C.; Medical Department of the University of Louisiana, New Orleans, 1878; member and past president of the Medical Society of the State of North Carolina; county superintendent of health, 1907-1913; since 1913 member of the state board of health; member of senate in 1885, and secretary of state, 1897-1901; aged 75; died, November 20, of pneumonia.

Hermon Camp Gordinier ⊕ Troy, N. Y.; Albany (N. Y.) Medical College, 1886; member of the American College of Physicians and the American Neurological Association; professor of medicine at his alma mater; on the staffs of the Mary McClellan Hospital, Cambridge, and the Samaritan Hospital; aged 66; died, October 19, of coronary thrombosis.

Charles Thomson Chamberlain, Natchez, Miss.; Medical Department of the Tulane University of Louisiana, New Orleans, 1902; member of the Mississippi State Medical Association and the American College of Surgeons; served during the World War; on the staff of the Chamberlain-Rice Hospital; aged 50; died, November 6.

Robert Ingram, Moscow, Ohio; Miami Medical College, Cincinnati, 1893; member of the American Psychiatric Association; for many years associate professor of psychiatry, University of Cincinnati College of Medicine; formerly on the staff of the Cincinnati General Hospital; aged 64; died, November 1, of cerebral hemorrhage.

Laura Viola Gustin Conibear, Attleboro, Mass.; Woman's Medical College of Pennsylvania, Philadelphia, 1874; member of the Massachusetts Medical Society; for twelve years member of the school board; formerly on the staff of the Sturdy Memorial Hospital; aged 78; died, November 3, of abdominal carcinoma.

Henry Mortimer Cunningham, Vancouver, B. C., Canada; Columbia University College of Physicians and Surgeons, 1895; member of the American Laryngological, Rhinological and Otological Society, Pacific Coast Oto-Ophthalmological Society and the American College of Surgeons; aged 64; died, September 6.

Henry Hubbard Pelton, New York; Columbia University College of Physicians and Surgeons, New York, 1898; veteran of the Spanish-American and World wars; formerly on the staffs of the Bellevue and Roosevelt hospitals; aged 59; died, November 11, of cerebral thrombosis.

Fritz Rosenbladt, Council Bluffs, Iowa; State University of Iowa College of Medicine, Iowa City, 1904; member of the Nebraska State Medical Society; served during the World War; aged 55; died, November 8, in the Covenant Hospital, Omaha, of heart disease.

John Eayre Robison, Frankfort, Ind.; Medical College of Indiana, Indianapolis, 1901; member of the Indiana State Medical Association; served during the World War; on the staff of the Clinton County Hospital; aged 59; died, November 14, of heart disease.

Frederick Adelbert Swartwood ⊕ Waseca, Minn.; University of Michigan Medical School, Ann Arbor, 1886; formerly mayor; member of the school board; on the staff of the Waseca Memorial Hospital; aged 69; died, November 12, of heart disease.

Franklin Harris Lackey, Fallston, N. C.; University of Maryland School of Medicine, Baltimore, 1915; member of the Medical Society of the State of North Carolina; aged 41; died, November 15, in the Shelby (N. C.) Hospital, of cerebral hemorrhage.

Ralph A. Harding, Reading, Pa.; Medical Department of Columbian University, Washington, D. C., 1895; member of the Medical Society of the State of Pennsylvania; aged 58; died, October 19, as the result of accidentally inhaling hydrogen cyanide gas.

Ruth Addie Gay, Oklahoma City, Okla.; Medical Department of Drake University, Des Moines, Iowa, 1897; Woman's Medical College of Pennsylvania, Philadelphia, 1904; aged 60; died, October 31, of cerebral hemorrhage and arteriosclerosis.

Jesse Badner, Jamaica, N. Y.; University and Bellevue Hospital Medical College, New York, 1925; member of the Medical Society of the State of New York; aged 28; died, October 31, in the Jamaica Hospital, of epidemic encephalitis.

Herbert Helmuth Holderman ⊕ Shenandoah, Pa.; Jefferson Medical College of Philadelphia, 1916; chief surgeon on the staff of the Locust Mountain State Hospital; aged 37; was instantly killed, November 4, in an automobile accident.

Clifford John Abbott, Holland, Mich.; Hahnemann Medical College and Hospital, Chicago, 1903; member of the Michigan State Medical Society; on the staff of the Holland City Hospital; aged 60; died suddenly, October 12, of heart disease.

Samuel Thomas Bell, Alpena, Mich.; Trinity Medical College, Toronto, Ont., Canada, 1886; member of the Michigan State Medical Society; on the staff of the Donald McRae Hospital; aged 69; died suddenly, November 5, of heart disease.

David R. Perkins, Marshville, N. C.; Baltimore Medical College, 1903; member of the Medical Society of the State of North Carolina; aged 52; died, November 12, in the Ellen Fitzgerald Hospital, Monroe, of carcinoma of the small intestine.

Erton Edwin Poynor, Stilwell, Okla.; University of Arkansas School of Medicine, Little Rock, 1904; member of the Oklahoma State Medical Association; aged 49; died suddenly, November 12, in Louisville, Ky., of heart disease.

Hugo Frederic Maetke, Dayton, Ohio; Medical Department of Columbia College, New York, 1892; member of the Ohio State Medical Association; aged 60; died suddenly, November 10, in Miami, Fla., of cerebral hemorrhage.

John S. Martin, Muncie, Ind.; Homeopathic Hospital College, Cleveland, 1883; member of the Indiana State Medical Association; for many years member of the school board; aged 78; died, October 7, of cerebral hemorrhage.

Fred Elmer Bryar, Concord, N. H.; Dartmouth Medical School, Hanover, 1894; member of the New England Society of Psychiatry; on the staff of the State Hospital; aged 59; died, October 25, in Boston, of bronchopneumonia.

Charles Augustus Short, San Jose, Calif.; Northwestern University Medical School, Chicago, 1915; member of the California Medical Association; served during the World War; aged 40; died, October 26, of heart disease.

John Patrick Redmond ⊕ Cedar Rapids, Iowa; Northwestern University Medical School, Chicago, 1903; served during the World War; formerly city physician; aged 52; was found dead, November 7, of aneurism.

Walter Joseph O'Keefe ⊕ Providence, R. I.; University and Bellevue Hospital Medical College, New York, 1910; aged 44; died, October 10, of *Staphylococcus albus* septicemia as the result of a carbuncle of the upper lip.

Arthur Wayland Slaught, Des Moines, Iowa; Chicago Homeopathic Medical College, 1887; formerly county coroner and member of the state legislature; aged 75; was found dead in bed, October 28, of coronary sclerosis.

Ralph Frank Goetter, Colville, Wash.; St. Louis University School of Medicine, 1915; member of the Washington State Medical Association; served during the World War; aged 40; died, October 5, of pneumonia.

James M. Caskie, Remington, Va.; College of Physicians and Surgeons, Baltimore, 1880; member of the Medical Society of Virginia; aged 70; died, November 4, of injuries received when he was struck by an automobile.

Louis P. Faust ⊕ Schenectady, N. Y.; New York Homeopathic Medical College, 1877; for many years member of the school board; on the staff of the Ellis Hospital; aged 75; died, November 8, of cerebral hemorrhage.

William Henry Sutherland, Rochester, N. Y.; Cornell University Medical College, New York, 1900; member of the Medical Society of the State of New York; aged 52; died, November 8, of chronic myocarditis.

Julius Edward Claussen, Beatrice, Neb.; Rush Medical College, Chicago, 1883; Medical Department of the University of the City of New York, 1888; aged 75; died suddenly, September 30, of organic heart disease.

William Josiah Parmelee, Springfield, Mass.; Medical Department of the University of the City of New York, 1890; member of the Massachusetts Medical Society; aged 72; died, October 28, of coronary thrombosis.

Charles H. Humphreys, Dayton, Ohio; Medical Department of Columbian College, Washington, D. C., 1869; member of the Ohio State Medical Association; aged 85; died in November, of chronic myocarditis.

Bryant Addison Gover, Burnside, Ky.; Hahnemann Medical College and Hospital of Philadelphia, 1930; aged 27; died, October 4, in the Somerset (Ky.) General Hospital, of injuries received in an automobile accident.

Thomas Jefferson Murray, Butte, Mont.; Jefferson Medical College of Philadelphia, 1879; member of the American College of Surgeons; aged 75; died, November 1, of arteriosclerosis and cerebral thrombosis.

Davis P. Borden, Paterson, N. J.; Eclectic Medical College of the City of New York, 1873; for many years member of the state board of medical examiners; aged 80; died, November 13, of chronic myocarditis.

George Allen Rush, Kansas City, Mo.; University Medical College of Kansas City, 1907; member of the Missouri State Medical Association; aged 47; died, November 18, of poison, presumably self-administered.

Ralph Willis Herbert, Manasquan, N. J.; New York Homeopathic Medical College, 1881; formerly member of the board of health and school board; aged 72; died suddenly, October 22, of heart disease.

Samuel Herbert Malpas, Indianapolis; Kentucky School of Medicine, Louisville, 1893; member of the Indiana State Medical Association; aged 62; died, November 15, in St. Vincent's Hospital, of nephritis.

William Jackson Grady, Stephenson, Miss.; Memphis (Tenn.) Hospital Medical College, 1900; member of the Mississippi State Medical Association; aged 52; died, October 30, of cerebral hemorrhage.

James H. Lyons ⊕ Troy, N. Y.; Albany Medical College, 1890; past president of the Rensselaer County Medical Society; on the staff of the Leonard Hospital; aged 72; died, November 8, of heart disease.

George C. Taylor, Cambridge, Ohio; Starling Medical College, Columbus, 1898; aged 54; died suddenly, November 18, in the Good Samaritan Hospital, Lexington, Ky., of acute dilatation of the heart.

Alfred Bernard Jordan, Albany, Calif.; University of Michigan Homeopathic Medical School, Ann Arbor, 1890; University of Illinois College of Medicine, Chicago, 1902; aged 71; died, October 11, of pneumonia and diabetic acidosis.

Elias Sheridan McCord, Delmar, Iowa; Medical Department of Drake University, Des Moines, 1894; formerly county coroner; mayor of Delmar; aged 62; died, November 10, in Clinton, of pneumonia.

Herbert Kilpatrick, Washington, La.; Medical Department of the Tulane University of Louisiana, New Orleans, 1891; aged 67; died, October 30, of bronchopneumonia, myocarditis and diabetes mellitus.

J. Martin Voorhees, Detroit; Long Island College Hospital, Brooklyn, 1897; aged 60; died, October 30, as the result of injuries received when the automobile in which he was driving, overturned.

Charles Maxwell MacGhee, Detroit; Tufts College Medical School, Boston, 1906; member of the Michigan State Medical Society; aged 57; died, August 3, of myocarditis and bronchopneumonia.

David Baird, Jr. ⊕ Florence, N. J.; Bellevue Hospital Medical College, New York, 1891; aged 61; died, November 7, in the Burlington County Hospital, Mount Holly, of streptococcic sore throat.

Joseph Raphiel, Houma, La.; Tulane University of Louisiana School of Medicine, New Orleans, 1913; aged 46; died, November 8, in the U. S. Marine Hospital, New Orleans, of chronic nephritis.

Nathan M. McCoin, Gainesboro, Tenn. (licensed, Tennessee, 1889); member of the Tennessee State Medical Association; aged 72; died, November 3, of bronchial asthma and myocarditis.

George Grant Smith, Parkman, Ohio; Western Reserve University School of Medicine, Cleveland, 1912; aged 64; died, October 31, in a hospital at Cleveland, of pneumonia, following an operation.

Giuseppe Tartaro, Buffalo; Royal University of Palermo Faculty of Medicine and Surgery, Palermo, Italy, 1895; served during the World War; aged 59; died, October 12, of cerebral hemorrhage.

Elmer Ellsworth Brown ⊕ Bangor, Maine; Medical School of Maine, Portland, 1888; on the staff of the Eastern Maine General Hospital; aged 69; died in September, of angina pectoris.

Louis J. Paris, Burlington, Vt.; University of Pennsylvania School of Medicine, Philadelphia, 1888; aged 66; died, November 9, in the Mary Fletcher Hospital, of heart disease.

Nathaniel Corn, Pikeville, Ind.; Louisville (Ky.) Medical College, 1887; aged 79; died, November 8, in the Walker Hospital, Evansville, of injuries received in an automobile accident.

Ernest Orion Finney ⊕ Weiser, Idaho; University of Illinois College of Medicine, Chicago, 1906; aged 51; died, October 1, in Chicago, of myocarditis and coronary embolism.

Samuel Sterling Northington, South Hill, Va.; Jefferson Medical College of Philadelphia, 1881; member of the Medical Society of Virginia; aged 70; died, October 27, of heart disease.

Edwin Augustus Morse, Appleton, Wis.; Chicago Medical College, 1888; member of the State Medical Society of Wisconsin; aged 69; died, November 10, of coronary sclerosis.

Caleb Rodney Layton, Georgetown, Del.; University of Pennsylvania School of Medicine, Philadelphia, 1876; formerly member of the state legislature; aged 85; died, November 11.

George Nelson Lapham ⊕ Boston; Boston University School of Medicine, 1900; associate professor of diseases of the chest at his alma mater; aged 58; died, September 30.

John Davis Criss, Pittsburgh; University of Wooster Medical Department, 1879; member of the Medical Society of the State of Pennsylvania; aged 75; died, November 8.

Pressley Spurgeon Thomas, Great Falls, S. C.; Medical College of the State of South Carolina, Charleston, 1917; aged 38; died, November 12, in the Columbus Hospital.

Andrew Jackson Roquemore, Shreveport, La.; University of Louisville (Ky.) School of Medicine, 1886; also a druggist; aged 70; died, November 4, of cerebral arteriosclerosis.

Albert William Sherman, Burlington, Iowa; University of Michigan Medical School, Ann Arbor, 1889; aged 68; died, October 14, in a local hospital, of lymphatic leukemia.

John H. Randle, Covington, Ga.; Chattanooga (Tenn.) Medical College, 1899; member of the Medical Association of Georgia; aged 60; died, November 5, of pyelitis.

George W. Thompson, Stockwell, Ind.; Medical College of Indiana, Indianapolis, 1897; aged 62; died, November 1, in the Ross Sanatorium, Lafayette, of tuberculosis.

William Rundle Walters, Toronto, Ont., Canada; University of Toronto Faculty of Medicine, 1887; chairman of the board of education; aged 67; died, October 14.

Edwin C. Hamilton, Kankakee, Ill.; Starling Medical College, Columbus, 1885; on the staff of St. Mary's Hospital; aged 70; died, November 18, of myocarditis.

Charles D. McRae, Rochelle, Ga.; University of Maryland School of Medicine, Baltimore, 1889; formerly member of the state legislature; aged 66; died, October 3.

Zachary Taylor Holtsclaw, Larchwood, Iowa; State University of Iowa College of Medicine, 1881; aged 83; died, November 6, in Nampa, Idaho, of uremia.

Robert Taylor, Coscob, Conn.; Long Island College Hospital, Brooklyn, 1871; Bellevue Hospital Medical College, New York, 1874; aged 81; died, November 1.

Jasper Corn, Frazeysburg, Ohio; Cincinnati College of Medicine and Surgery, 1873; also a druggist; aged 82; died, November 14, of cerebral hemorrhage.

Dowling Benjamin, Camden, N. J.; University of Pennsylvania School of Medicine, Philadelphia, 1877; aged 81; died, November 20, of cancer of the bladder.

Israel P. Birney, Wheeling, W. Va.; Cincinnati College of Medicine and Surgery, 1879; aged 77; died, October 28, in the Wheeling Hospital, of arteriosclerosis.

Harry Houston Hughart, Tombstone, Ariz.; University College of Medicine, Richmond, Va., 1900; aged 54; died suddenly, November 3, of heart disease.

Theodore Dudley Rountree, Rockdale, Texas; University of Virginia Department of Medicine, Charlottesville, 1902; aged 50; died, October 5, in San Antonio.

Joseph Hannold McElHinney, Palm City, Calif.; Eclectic Medical Institute, Cincinnati, 1873; aged 80; died, October 4, in Hollywood, as the result of a fall.

Wallace A. E. De Beque ⊕ De Beque, Colo.; Denver College of Medicine, 1882; Civil War veteran; aged 89; died, September 10, of bronchopneumonia.

John McKinney Thornton, Denver; Medical College of Ohio, Cincinnati, 1873; aged 83; died, September 27, in Presbyterian Hospital, of chronic cystitis.

Hial A. Wheeler, Creswell, Ore.; State University of Iowa College of Medicine, Iowa City, 1881; formerly a clergyman; aged 76; died, October 12.

John S. Cook, Beecher City, Ill.; Missouri Medical College, St. Louis, 1880; also a minister; aged 81; died, October 22, of dilatation of the heart.

Abraham Behm Kauffman, Lancaster, Pa.; Hahnemann Medical College and Hospital of Philadelphia, 1903; aged 56; died, November 7, heart disease.

William I. Harkey, Ola, Ark.; University of Arkansas School of Medicine, Little Rock, 1893; aged 80; died, October 19, in a hospital at Little Rock.

Emma H. Butman, Toledo, Ohio; Homeopathic Hospital College, Cleveland, 1890; aged 81; died, November 16, as the result of a cerebral hemorrhage.

Mary Riddle Wilcox, Bala-Cynwyd, Pa.; Woman's Medical College of Pennsylvania, Philadelphia, 1891; aged 76; died, November 4, of angina pectoris.

William Rasbury Rankin, Montgomery, Ala.; Atlanta College of Physicians and Surgeons, 1901; aged 55; died, November 6, of heart disease.

Rose Finkelberg, Jackson, Mich.; Bennett College of Eclectic Medicine and Surgery, Chicago, 1908; aged 59; died, November 4, of carcinoma.

Caleb A. Montgomery, Avery, Iowa (licensed, Iowa, 1886); aged 79; died, November 16, of injuries received when he was struck by a truck.

Samuel Addison Bowles, Westphalia, Mo.; Kentucky School of Medicine, Louisville, 1883; aged 78; died, September 30, of arteriosclerosis.

Ivan T. Myers, Brandon, Miss. (licensed, Mississippi, 1907); aged 49; died suddenly, November 1, in a hospital at Jackson, of heart disease.

William R. Henderson, Detroit; Detroit College of Medicine, 1886; aged 70; died, November 5, in the Harper Hospital, of intestinal obstruction.

Buxton B. Williams, Greensboro, N. C.; University of Maryland School of Medicine, Baltimore, 1883; aged 70; died, October 5, of nephritis, uremia and heart disease.

Charles Joseph Hart, Pulaski, Ill.; St. Louis College of Physicians and Surgeons, 1910; aged 58; died, October 12, in Cairo, of chronic myocarditis.

George Pryor McCloud, Fountain City, Tenn.; Tennessee Medical College, Knoxville, 1890; aged 81; died, October 24, of lymphatic leukemia.

William Lockwood Thornton Addison, Toronto, Ont., Canada; University of Toronto Faculty of Medicine, 1898; aged 60; died recently.

William Lewis Chapman, Freeport, N. Y.; Bellevue Hospital Medical College, New York, 1893; aged 58; died, October 26, of myocarditis.

William E. Lawhead, Burlington, Iowa; College of Physicians and Surgeons, Keokuk, 1882; aged 74; died, October 13, in a local hospital.

John Blanchard Weever, Dallas, Texas; Jefferson Medical College of Philadelphia, 1858; aged 94; died, November 13, of bronchopneumonia.

Frederick Eugene Gullison, Yarmouth, N. S., Canada; McGill University Faculty of Medicine, Montreal, 1916; aged 40; died, October 3.

Corey Barton Cullison, Newark, Ohio; Starling Medical College, Columbus, 1891; aged 63; died suddenly, November 10, of heart disease.

Henry James Cartin ⊕ Johnstown, Pa.; Jefferson Medical College of Philadelphia, 1901; aged 61; died, October 30, of cerebral thrombosis.

Ada P. North, Rock Rapids, Iowa; Hahnemann Medical College and Hospital, Chicago, 1895; aged 66; died in October, of heart disease.

Lewis Hiram Tutt, Hannibal, Mo.; Bellevue Hospital Medical College, New York, 1888; aged 71; died, November 7, of heart disease.

Michael Edward Whelan, Roanoke, W. Va.; Kentucky School of Medicine, Louisville, 1893; aged 80; died, October 3, of carcinoma.

Edwin Boucelle Ferebee, Belcross, N. C.; College of Physicians and Surgeons, Baltimore, 1885; aged 65; died, September 25.

William Spencer Harrison, Overton, Nev.; Trinity Medical College, Toronto, Ont., Canada, 1884; aged 66; died, September 12.

Benjamin J. Shelton, Antioch, Tenn.; Medical Department, University of Tennessee, Nashville, 1882; aged 73; died, October 6.

Arnold Jolly, Florence, Ala.; Medical College of Alabama, Mobile, 1885; aged 69; died suddenly, September 29, of heart disease.

Edward Allan, Arthur, Ont., Canada; University of Toronto Faculty of Medicine, 1869; aged 85; died, September 30.

Adelia Bentley Barber, Los Angeles; New York Medical College and Hospital for Women, 1883; aged 79; died, October 4.

Lloyd Emerson Matter, Pasadena, Calif.; Rush Medical College, Chicago, 1904; aged 51; died, October 14, of rheumatic fever.

Benjamin F. Overmyer, Leiters Ford, Ind. (licensed, Indiana, 1897); aged 74; died, November 11, of pneumonia.

Elmer Ellsworth Scott, Ann Arbor, Mich.; Chicago Physio-Medical Institute, 1886; aged 67; died, September 29.

George D. Allen, Belleville, Wis. (registered, Wisconsin); aged 78; died, October 6, of malignant papilloma of the bladder.

Norbert P. Crawford ⊕ Pen Argyl, Pa.; Jefferson Medical College of Philadelphia, 1925; aged 30; died, October 18.

James McDowell, Pasadena, Calif.; Hospital College of Medicine, Louisville, Ky., 1880; aged 81; died, October 26.

Elijah Gilbert Howell, Bath Springs, Tenn. (licensed, Tennessee, 1889); aged 75; died, October 19.

Isaac N. Boyd, Pittsburgh; Eclectic Medical Institute, Cincinnati, 1885; aged 72; died, October 14.

Hiram I. Nance, Los Angeles; Rush Medical College, Chicago, 1877; aged 76; died in October.

Stephen A. Morse, Little Rock, Ark. (licensed, Arkansas, 1903); aged 80; died, October 18.

Bureau of Investigation

COLLECTION AGENCIES

The Experience of an Indiana Physician with the Robison National Clearing Company, Inc.

The short story that follows gives the experience of Dr. E. O. Price of Ladoga, Ind., with the Robison National Clearing Company, Inc., of Albany, N. Y., and New York City. At the outset, it should be stated that the contract which the Robison National Clearing Company uses in its collection service has many of the inequitable features of such contracts that The Journal has commented on at various times. The physician who signs such a contract assigns to the agency the accounts that he turns over to it; he agrees to pay the company 50 per cent on the first aggregate $100, 50 per cent on collections made through attorneys, 50 per cent on collections made in installments, 50 per cent on outlawed accounts, and 50 per cent on accounts that are withdrawn or settled by creditors. On all other collections, the physician agrees to pay 15 per cent. The contract further requires the physician to report immediately to the company any payments that are made direct to him and also to remit the company's commission at once. In addition, the company, under the contract, charges the doctor 50 cents for each account. The contract also states that after twelve months, any account that is not in process of adjustment, settlement or legal proceedings, will be released to the physician.

Among the inequitable clauses in this contract are first, the one that makes it in the interests of the agency to collect on installments; second, the one which makes it necessary for the physician to pay 50 per cent of the face value of any one of the accounts that he wishes to withdraw; third, the clause that makes it obligatory on the part of the physician immediately to send to the agency any money that may be paid to him direct, although there is nothing requiring the company to render any accounting of moneys collected by it at any definite stated intervals.

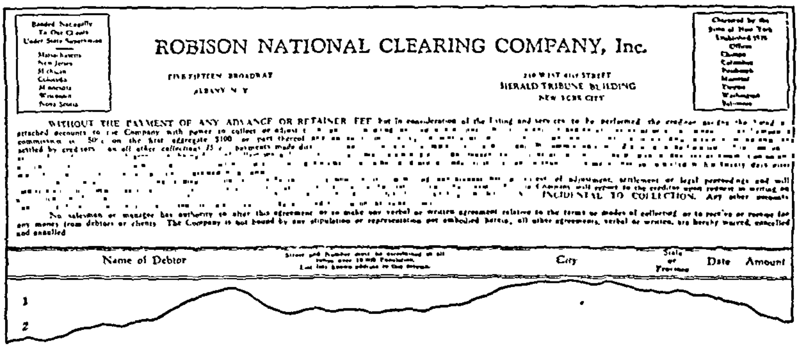
In June of this year, The Journal received a letter from Dr. E. O. Price of Ladoga, Ind., reading in part as follows:

> "*To the Editor:*—On May 16, 1930, one calling himself P. L. Rosenkrans came into my office and represented himself as collecting names of 'debtors' (bad-pay people), and saying he had covered Ohio and was making a canvass of Indiana; a blacklist, in fact, though he did not so denominate it. I told him I did not care for any such thing. He stated explicitly that he had no contracts to sign, represented no collecting agency, etc.
>
> "He then began calling off local names. Some I knew and more I did not know; some owed me or had in the past, most did not and I so told him. I was not asked to, nor did I sign or verbally make any contract. Some time after he left some of the people, at least, whose names he had read over to me, got a dun and I received a long list of names from the Robison National Clearing Company, Inc., 'Collection Engineers,' 515 Broadway, Albany, N. Y., asking me to O. K. the list.
>
> "I directed my attorney to notify the Robison company that I had not authorized them to make any collections for me nor given them any list of names for that purpose. In due time I received a letter, stating that they were very much surprised at my letter and enclosing a blank contract; the 'original' contract they claimed they held with my signature attached. Such a contract they absolutely do not have, none even having been asked for by the alleged P. L. Rosenkrans. Now, if you can give me any information about these people, I should like to know what their game is."

On receipt of Dr. Price's letter, the Bureau of Investigation wrote to the Robison National Clearing Company, briefly outlining Dr. Price's complaint and asking for an explanation. In reply came a letter from the general manager of this company, stating that they had in their possession an "original contract" bearing the signature of Dr. Price, which had been sent to them by their representative, P. L. Rosenkrans. They said, further, that they were unaware of any of the representations made by Rosenkrans and assumed that the list of claims was authentic; that they would cooperate with the Bureau of Investigation of the American Medical Association in looking into the matter; that they desired to have the name of the bank with which Dr. Price did business, so that they could send the original contract to the bank for the purpose of having Dr. Price call and see the signature; and that should the company find the signature to be other than that of Dr. Price, they would use this fact as evidence against Rosenkrans.

In due course, the contract was sent to the Ladoga State Bank, with which Dr. Price did business. The company, in the meantime, asked the Bureau of Investigation to advise Dr. Price to prepare and send along a list of all payments that he had received to date from the list of debtors. The Bureau wrote the company that it could see no reason for asking Dr. Price to go to that trouble, for the reason that the doctor had declared unequivocally that he had entered into no contract with the company and was under no obligation to furnish such a report.

Some days later the Bureau of Investigation received a letter from Dr. Price, enclosing duly executed affidavits from (1) Dr. Price himself; (2) a local justice of the peace who had known Dr. Price for thirty-five years; (3) from the owner of the local telephone company, who was also an insurance man, and with whom the doctor had transacted business for more than thirty years; (4) from the local banker, who had known Dr. Price for thirty-five years and who was thoroughly acquainted with the doctor's signature. All of these affidavits declared that the signature on the contract sent by the Robison National Clearing Company, Inc., was not the signature of Dr. E. O. Price.



ROBISON NATIONAL CLEARING COMPANY, Inc.

FIVE FIFTEEN BROADWAY
ALBANY N Y

HERALD TRIBUNE BUILDING
NEW YORK CITY

WITHOUT THE PAYMENT OF ANY ADVANCE OR RETAINER FEE

No salesman or manager has authority to alter this agreement or to make any verbal or written agreement relative to the terms or modes of collecting or to receive or receipt for any money from debtors or clients. The Company is not bound by any stipulation or representation not embodied herein, all other agreements, verbal or written, are hereby waived, cancelled and annulled

	Name of Debtor		City	State or Province	Date	Amount
1						
2						

The Bureau of Investigation then wrote the Robison National Clearing Company, Inc., stating that these affidavits had been received and enclosing copies of them. In reply, the Robison concern thanked the Bureau for the work that it had done and enclosed a copy of a letter that that company had just written under the same date to Dr. Price. This letter stated that on the basis of the information furnished it by the American Medical Association, the company was convinced "that there has been some underhand work done by Mr. Rosenkrans" and that it had discontinued any further action on the claims and the doctor's debtors would hear nothing further from the company. The letter added, however, that the Robison National Clearing Company felt that, under the circumstances, it believed the doctor would agree that the company should retain 50 per cent of the amount that it had collected, and that if this was satisfactory to the doctor, the company would, on hearing from him, send him a check for one-half the money that had been collected! The Bureau of Investigation, in reply to this, wrote the company that it was surprised that it should take such an attitude and added:

> "We venture to say that no honorable business concern that had done a citizen a wrong through the criminal actions of its representative, would think of asking that citizen to help pay some of the expense to which the business concern had been put through its representative's criminality."

This letter brought a somewhat caustic reply from the Robison National Clearing Company, suggesting in part that the Bureau of Investigation "spend a little of its good money looking up the records of some of the doctors that you are defending (eliminating Dr. Price from this statement), whose names are to be found in the files of every collection agency." However, the important fact is that the company sent Dr. Price a check for the full amount that it had collected.

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

TECHNIC OF STERILIZATION OF WOMEN

To the Editor:—In The Journal, October 25 (p. 1282), you mentioned the method suggested by R. L. Dickinson for sterilizing women. This method results in an occlusion of the tubal openings by means of an electric cautery. In my books on gynecology I do not find any reference to this procedure. If you can give me any information in regard to the technic used it will be greatly appreciated.

Paul Levi, M.D., Gowanda, N. Y.

Answer.—The method of sterilization suggested by Dickinson and used by him since 1912 is an office procedure. Its aim is to produce occlusion of both fallopian tubes at their entrance into the uterine cavity, and for this purpose an electrical cautery is used. Dickinson describes his method as follows: "Before sterilizing by the cautery wire (or by electrocoagulation), the shape and size of the cavity of the uterus must be defined. The uterine sound gives a very fair idea of the upper corner, whether acute angled, rounded or domed. In the latter cases the vestibule of the tube is difficult or impossible to find. For such conformations, visualization, as by roentgen shadow from injected iodized oils, is needed, or else the same skill with the new hysteroscopes of Rubin and Gauss and of Mikulicz-Radecki and Freund, as has been attained with their patent, the cystoscope. With the aid of the eye it may be possible, in the future, also to dilate the minute uterine funnel as accurately as the mouth of the ureter can be, should it be desired to reopen a cautery stricture later. . . . After the length of the cavity is determined, the cautery sound is slid up against the external os so as to admit only this length. The possibility of pushing in farther and perforating is prevented by the sliding shoulder fixed where needed. When the cautery tip has been nestled into one upper angle of the uterus, the current is turned on for from ten to thirty seconds, according to the vascularity of the lining, a succulent uterus needing a longer application of the current. A test is made by starting to draw the sound away. It should adhere rather firmly and bring away a shriveled fragment of tissue all about it. Only in case the uterus relaxes, as it does during curetting, need one consider new sounding and renewed cauterization at this session."

Illustrations and a more detailed description may be found in the following articles by Dickinson:

Simple Sterilization of Women by Cautery Stricture of the Intra-Uterine Tubal Openings, *Surg. Gynec. Obst.* **23**: 203 (Aug. 16) 1916.

Sterilization Without Unsexing, The Journal, Feb. 2, 1929, p. 373.

PAROXYSMAL TACHYCARDIA

To the Editor:—A woman, aged about 45, weighing about 200 pounds (90 Kg.), has had for the last five years what she calls spells of palpitation of the heart. The spells come on about once or twice a month. Her blood pressure is 225 systolic and 110 diastolic. There is a trace of albumin in the urine. The patient's pulse suddenly goes up to about 160 or 200. The patient is perfectly conscious and shows no distress with the exception of a tight feeling in the chest. These attacks may last from an hour to six or ten hours. The patient usually stays in bed while they last. The standard drugs for cardiac asthma show no effect on the patient's condition. However, when the patient takes morphine and begins to vomit, the spell stops in an instant and she feels perfectly well until another spell comes on, weeks later. Many things have been tried. The last drug I tried was an intravenous administration of a theophylline preparation but without any effect. The patient's condition was named paroxysmal tachycardia, but of course this name does not enlighten me any. Do you have any suggestion as to the treatment in this patient? Between the attacks her heart is perfectly compensated without any evidence of organic or functional trouble. Please omit name.

M.D., Iowa.

Answer.—If the pulse is regular, the diagnosis is probably that of a paroxysmal tachycardia. With such a history and such observations, this might be of either auricular or ventricular origin. It is important to know which, because the auricular type is of minor significance and the ventricular type is of much more serious portent. With a history of this kind, and over so long a period, one would assume that this is of auricular origin. If possible, graphic records should be obtained during the attack. The type of ectopic beats occurring between the attacks, whether of auricular or of ventricular origin, is presumptive evidence of the origin of the attacks. Such ectopic beats may occur rarely, and differentiation is uncertain at best.

Paroxysmal tachycardia is a rapid, regular rhythm, usually about 180 a minute, which does not change rate on change of posture or exertion, and which begins instantly and ceases instantly. The patient usually mentions the instantaneous onset, but the instantaneous offset may be masked by symptoms persisting a short time after the pulse returns to normal.

It would seem more probable that the attacks are of auricular origin. No drug is of value during the attack. Daily doses of quinidine may prevent the attacks, but the constant use of a depressant drug is of doubtful propriety in any case of paroxysmal tachycardia and especially so here, when the attacks are so far apart.

Emesis, or nausea, as in this case, will frequently stop the attacks and can be induced by placing the finger in the pharynx. Easier methods are often of avail, such as bending over in the sitting posture with the head between the knees; taking a deep breath and holding it; contracting the abdominal muscles so as to increase intra-abdominal pressure; coughing, and many other methods, which patients frequently discover themselves. If the physician will stand behind the patient during an attack and compress the carotid artery on one side between his finger and the cervical spine, the attack will frequently cease, owing possibly to vagus stimulation but more probably to stimulation of the carotid sinus. Swallowing a large bolus may stop the attack, or a large elastic capsule. Attacks are frequently precipitated by errors in diet, and this factor should receive attention.

If the pulse is absolutely irregular, the attack is probably an attack of paroxysmal auricular fibrillation. In such cases the patient should be put at rest and no drugs used until one is assured by the duration of the attack that the pulse is not going to return to normal, when digitalis may be started.

Paroxysmal auricular flutter occurs, but the rate in this case is too rapid.

Paroxysmal tachycardia of ventricular origin is usually consequent on coronary damage, especially a thrombosis, and its recognition is of the greatest importance.

PRECORDIAL PAIN

To the Editor:—A number of my patients have complained of a sharp sticking pain in the precordium of momentary duration and at infrequent intervals. Physical signs are absent, and I have ruled out organic disease of the heart, muscle, bone and nerve. In spite of its common occurrence I can find nothing in the literature concerning the nature of the condition. Can you refer me to any? Please use initials if answered in Queries and Minor Notes.

M.D., New Jersey.

Answer.—Excellent discussions on this variety of precordial pain may be found in "Diseases of the Heart" by James Mackenzie (Oxford Medical Publications, ed. 3, 1913, p. 57) and in "Heart Disease" by Sir William H. Broadbent (New York, William Wood & Co., ed. 4, 1906, p. 381).

Precordial pain in the absence of signs and symptoms of any of the cardiopathies may be the result of toxic influences, as tobacco or coffee, of direct pressure on the heart by a dilated stomach or colon, or of emotional or depressive states. As demonstrated by Mackenzie and by Head, it may furthermore be reflexly produced by derangements of any of the viscera and as such has been designated as "reflected pain." The explanation offered for this misreference is that since the viscera are insensitive to pain-producing stimuli, the pain is referred to the skin region that is supplied by the spinal segment from which the organ in question receives its sensory fibers, the misreference being due to a diffusion in the nerve centers. By amending any visceral abnormality, eliminating toxic agents and assuring the patient that there is no disease of the heart, thereby dispelling his apprehension, the disappearance of this symptom may be anticipated.

TREATMENT OF VARICOSE ULCER

To the Editor:—I have been treating a chronic varicose leg ulcer but cannot clean it up. This patient has never had any trauma, infection of the lower extremity, syphilis or phlebitis. Her occupation for a long time required constant standing. The superficial veins above are involved. The Trendelenburg sign is absent. I have used salves, liquids, light therapy and Unna's paste, and recently vein injection.

A. B. Barker, M.D., Peoria, Ill.

Answer.—Failure for a chronic varicose ulcer to heal in spite of supportive and injection treatment may be due to several causes. In the first place, it may not be a true varicose ulcer. The presence of dilated veins above the ulcers does not necessarily mean that the ulcer is caused by the veins, especially if the Trendelenburg sign is negative. If the reflux of blood from above cannot be properly demonstrated, the obliteration of veins cannot have much influence on the healing of the ulcer. The exclusion of specific infections such as syphilis, tuberculosis and different mycoses is important. The size and amount of fibrosis around the ulcer may hinder a proper epithelization. The site of the ulcer is also of influence. In certain areas, such as above the anterior tibial margin or below the malleoli, the skin is on a stretch, the margins easily retract, and the blood supply is comparatively poor. A peripheral arteriosclerosis may also hinder healing of the defect.

In such rebellious cases, if no specific etiology is found, the patient should be handled surgically and by men who have had enough experience in plastic surgery. The ulcer must be cleared up with hot boric acid dressings. When the granulations take on a healthy appearance and a scraping shows an absence or great diminution of bacteria, the callous margin of the ulcer is excised and a skin graft is applied. Whether a Thiersch graft, a pinch graft or a pedicled flap is used will depend on the individual case. Following the graft, Unna's paste boots have to be worn for several weeks.

OXALURIA

To the Editor:—For some time I have been seeing cases of oxaluria, usually accompanied by indicanuria plus 4. The symptoms have varied from acute, paroxysmal pain, as in ureteral colic, to chronic, indefinite aches and pains. By means of nitrohydrochloric acid, followed up by magnesium oxide and potash, combined in equal parts, I have been able to relieve the major symptoms of these patients, but have found that the cessation of the taking of these remedies is immediately followed by the reappearance of the calcium oxalate crystals and by pains. It is quite evident that in oxaluria there is faulty metabolism. Can you advise me *how to handle these cases?*

Rolla Camden, M.D., Parkersburg, W. Va.

Answer.—The excreted oxalates appear to be in part exogenous in origin and in part endogenous. The former are derived from such foodstuffs as contain large quantities of oxalates, such as asparagus, apples, cabbage, grapes, lettuce, rhubarb, spinach and tomatoes.

Excessive excretion of endogenous oxalates has been variously considered to be connected with faulty metabolism of all types of foodstuffs—proteins, fats and carbohydrates. Oxaluria occurs in some liver diseases and is reported to be present in diabetes mellitus.

Some workers have reported that the ingestion of certain strains of colon bacilli found in the feces in cases of oxaluria, produces oxaluria in normal subjects.

DELAY IN DEVELOPMENT OF SPEECH

To the Editor:—A well developed child, aged 2 years, who is of proper height and weight, can find her way about the entire home, eats alone, knows people, but still does not talk. She talks and tries to repeat each word and knows the names of things but pronounces only half of the words. For instance, for "only" she says "on"; but she can say "ly" because I tried her by asking her to say "Leo," and all she said was "Lee." Please advise what could be the cause of it, and what there is to be done. Kindly omit name and address.

M.D., New York.

Answer.—From the samples given, it is not possible to reach a conclusion as to the cause. The fact that the child is well developed and shows good comprehension in proportion to her age would *tend to rule out an organic disease or defect with* resultant aphasia. Motor speech is sometimes much delayed in development and yet will evolve fully later. The best plan would probably be to have the child studied by a physician with a special knowledge of the speech disorders of childhood.

HYPOTHYROIDISM

To the Editor:—A man, aged 30, is unable to concentrate properly, lacks initiative, and is forgetful, sluggish of mind and backward. Would thyroid treatment be of benefit to him? What line of treatment would you suggest in this case? Please omit name.

M.D., Illinois.

Answer.—While this patient may be deficient in thyroid, a study of the basal metabolism is necessary before making a diagnosis of hypothyroidism. In the event that the metabolism is found to be low, thyroid will probably be of considerable benefit. The dosage cannot be ascertained except by the method of careful investigation of each patient. It is well known that one-half grain (0.03 Gm.) of thyroid three times a day is usually a safe and small dose, although it may be too big for some patients. However, it is usually a good starting point, the dose to be increased or diminished according to the reaction of the patient.

If there is no metabolic evidence of thyroid disease, the patient can still be given small doses of thyroid, but one would suggest that an examination of the mentality of the patient might be of considerable value.

BITES BY APHIS LION

To the Editor:—A prolonged drought, as a disturbance, digs deep into the daily web of life. The aphis lion (*Chrysopidae*) usually finds aphides enough and to spare; but not this dry year. As a result, he turned to anything bearing blood and I have known of six or more bites this summer. About the first week in August, sitting under a large white oak tree in my yard, I felt a sharp bite on the wrist and looked to find, to me, a new form of insect sinking his "beak" into the flexor aspect of my wrist so vigorously and with such manifest enjoyment that I became more interested than angry. He was a yellowish, spotted, canoe-shaped larva of some kind about 5 or 6 mm. long, with a pair of long curved, almost parallel mandibles, now covered with blood, with which he was tearing the flesh. Some movement of mine made him move about an inch away, where he started again, nothing daunted. The pain was more like a bite than a sting, but the after-results indicated some new and novel toxin. Interested, I let him suck his fill at the second site, and then I bottled him for identification—with the result mentioned. An hour later there was an intense burning pain, worse than any mosquito bite, with an areola an inch or more in diameter around the first bite and almost none around the second, showing seemingly a mosquito-like initial injection of some anticlotting globulin. The next day the two were equally inflamed and almost purpuric in tint. It was not until the fourth day that the inflammation began to decline. Two friends who saw the "bug" had experiences almost as bad, and one or two others who visited me had "strange bites" of untoward severity. Has this experience been found elsewhere? I am anxious to know.

P. B. Barringer, M.D., University, Va.

Answer.—A careful search of the modern textbooks of medical entomology and the most promising current literature in entomology fails to reveal any published cases in which the aphis lion (*Chrysopidae*) has bitten man. In spite of this, however, several American entomologists on personal inquiry note that they have been bitten by these insects. From their experience this seems to be the usual result if the insect is given the opportunity.

SENSES OF SMELL AND TASTE

To the Editor:—I have a friend, a man of intelligence and university training, a horticulturist, whose nasal structures, including the skin, mucosa and cartilage, were completely destroyed fifteen years ago by tuberculosis and subsequent roentgen burns. All lesions are now completely healed but the patient is entirely lacking in the sense of smell, which, he says, was unusually keen prior to his illness. He has tested himself with a number of things, notably hydrogen sulphide, ammonia and garlic, and from these he receives no aroma sense whatever, though he says that the two latter substances cause a burning sensation within the nasopharynx. *In spite of his deformity, he tells me that his sense of taste is in no way impaired. He can appreciate the flavors of all foods* and drinks as well as ever and he is very particular about his brand of smoking tobacco. I would appreciate any comments you might make on this case since I had always understood that the so-called taste of things—with the exception of salt, sweet, bitter, sour—was dependent on the sense of smell.

Greenshaw-Mandel, M.C., Morelos, Mexico.

Answer.—On the basis of what is known today, it is not quite correct to say that the sense of taste is dependent on the sense of smell. These two senses have separate peripheral end organs in specific regions of the nasal mucous membrane and specific regions in the mucous membrane of the tongue and the pharynx. They have separate conduction paths to the brain *and they have in all probability geographically distinct areas* in the cerebral cortex for conscious elaboration of the afferent impulses. But in the normal individual with both of these senses intact and functioning there are in many cases both fusion and confusion of these senses in consciousness developed apparently because of the fact that substances that give taste also contain volatile elements that give rise to the sense of smell. It is a common experience that persons with head colds, and therefore with edema of the nasal mucous membrane interfering with the free passage of the air to the olfactory regions of this membrane, and decreased sensitiveness of the olfactory cells themselves, frequently report a change in or an absence of taste in foods or drinks ingested. These are acute conditions and the statement of absense of taste is exaggerated. If such a condition becomes chronic, the individual would ultimately learn to recognize the taste sense per se. In other words, it appears that fusion and confusion of taste and smell is a matter of individual experience and this condition usually persists through life, but it is possible to differentiate this fusion and confusion by reeducation. Therefore there is nothing extraordinary in the case described, especially when it is remembered that the man is comparing his present taste of things with what he remembers of the taste of the same things before the destruction of the nasal membranes. Comparison of such memories is never accurate. In most people it would seem that the biggest factor in the choice of a brand of smoking tobacco depends on odor rather than taste, except for such elements as a burning sensation in the mouth produced by some brands of tobacco. It is difficult to determine the actual basis for the subject's choice of tobacco in the total absence of smell. It may be experience prior to his loss of the sense of smell. It may be the experience of others. It may be advertising. But it must be admitted that a thorough study of the taste sense in intelligent persons with prolonged absence of the sense of smell has not been made.

Washington: Seattle, Basic Science, Jan. 8-9, 1931. Regular, Jan. 12-13, 1931. Dir., Mr. Charles Maybury, Olympia, Wash.

Wisconsin: Regular, Madison, Jan. 13-15, 1931. Sec., Dr. R. E. Flynn, 315 State Bank Bldg., La Crosse, Wis.

Missouri June Examination

Dr. James Stewart, secretary of the Board of Health of Missouri, reports the written examination held at St. Louis, June 11-13, 1930. The examination covered 14 subjects and included 100 questions. An average of 75 per cent was required to pass. One hundred and forty-nine candidates were examined and passed. The following colleges were represented:

PASSED

College	Year Grad.	Per Cent
Howard University School of Medicine	(1929)	81.2, 85.6
Northwestern University Medical School	(1930)	85.5
Rush Medical College	(1930)	85.5
State University of Iowa College of Medicine	(1930)	81.5
University of Kansas School of Medicine	(1930)	82.3, 86.6, 87.1
University of Michigan Medical School	(1929)	85.5
St Louis University School of Medicine	(1929)	79.1, 80.1, 83.8, 84.1, 84.2, 85, (1930) 79.8, 80.5, 80.7, 81.5, 82, 82.1, 82.2, 82.4, 82.5, 82.6, 82.7, 82.7, 82.8, 82.8, 83, 83, 83, 83.2, 83.2, 83.2, 83.2, 83.5, 83.6, 83.7, 83.8, 83.8, 83.8, 83.9, 84.1, 84.1, 84.2, 84.2, 84.2, 84.2, 84.4, 84.5, 84.5, 84.6, 84.9, 85, 85, 85.1, 85.1, 85.3, 85.3, 85.4, 85.4, 85.4, 85.5, 85.7, 85.9, 86.1, 86.1, 86.1, 86.2, 86.5, 86.7, 86.8, 87.1, 87.3, 87.9, 88.2, 88.4
Washington University School of Medicine	(1926)	85.3, (1928) 84.9, (1929) 80.8, 81.7, 82.8, 84.1, 84.3, 85.1, 86.7, 86.9, 88.3, 89.1, 96.3, (1930) 82.2, 82.9, 83, 83, 83.2, 83.3, 83.4, 83.7, 83.7, 83.8, 84, 84.2, 84.3, 84.5, 84.8, 85, 85, 85.1, 85.1, 85.2, 85.4, 85.4, 85.4, 85.5, 85.6, 85.7, 85.7, 85.7, 85.9, 86, 86.1, 86.2, 86.3, 86.4, 86.5, 86.5, 86.6, 86.8, 86.8, 87, 87.1, 87.5, 87.5, 87.5, 87.7, 88.4, 89.2, 89.5, 89.7, 90, 90.2
Creighton University School of Medicine	(1930)	81.8
University of Pennsylvania School of Medicine	(1928)	82.2
Meharry Medical College	(1929)	79.1
University of Tennessee College of Medicine	(1930)	83.7
Marquette University School of Medicine	(1930)	85.8
University of Wisconsin Medical School	(1929)	80.3
Dragomanov Institute, Kiev	(1922)	75 *

* Verification of graduation in process.

Dr. Stewart also reports 35 physicians licensed through reciprocity with other states and 8 by the endorsement of credentials, from Jan. 1 to July 30, 1930. The following colleges were represented:

LICENSED BY RECIPROCITY

College	Year Grad.	Reciprocity with
University of Arkansas School of Medicine	(1929)	Arkansas
Emory University School of Medicine	(1921)	Georgia
Chicago Medical College	(1927)	Illinois
Loyola University School of Medicine	(1916)	Illinois
Northwestern University Medical School	(1906) (1920)	Illinois
State Univ. of Iowa College of Med.	(1923) (1928) (1929)	Iowa
University of Louisville School of Medicine	(1929)	Kentucky
Univ. of Kansas Sch. of Med.	(1925) (1927) (1928-2) (1929)	Kansas
University of Michigan Med. Coll.	(1914) Michigan, (1926)	Minnesota
University of Minnesota Medical School	(1928)	Minnesota
Barnes Medical College	(1910)	Arkansas
Washington University School of Medicine	(1927)	Illinois
Creighton University School of Medicine	(1924) (1926)	Kansas
University of Nebraska College of Medicine	(1924) (1926)	Nebraska
University of Buffalo School of Medicine	(1911)	New York
Jefferson Medical College	(1927)	Penna
University of Pennsylvania School of Medicine	(1928)	Kansas
Meharry Medical College	(1909) Georgia, (1928) (1929)	Tennessee

Utah June and July Examination

Mr. S. W. Golding, director of the Department of Registration of Utah, reports the written examination held at Salt Lake City, June 30 and July 1, 1930. The examination covered 10 subjects and included 100 questions. An average of 75 per cent was required to pass. Six candidates were examined and passed. The following colleges were represented:

PASSED

College	Year Grad.	Per Cent
Northwestern University Medical School	(1930)	88
Creighton University School of Medicine	(1929) 83, (1930)	85 *
Syracuse University College of Medicine	(1929)	82
University of Pennsylvania School of Medicine	(1929)	88
University of Wisconsin Medical School	(1929)	80

Mr. Golding also reports 4 physicians licensed through reciprocity with other states at the same meeting. The following colleges were represented:

LICENSED BY RECIPROCITY

College	Year Grad.	Reciprocity with
State University of Iowa College of Medicine	(1928) (1929)	Iowa
University of Louisville School of Medicine	(1880)	Missouri
University of Tennessee College of Medicine	(1929)	Tennessee

* Certificate to practice will not be granted until after completion of internship.

Ohio June Examination

Dr. H. M. Platter, secretary of the State Medical Board of Ohio, reports the oral, written and practical examination held at Columbus, June 9-12, 1930. The examination covered 10 subjects and included 85 questions. An average of 75 per cent was required to pass. One hundred and ninety-eight candidates were examined, 197 of whom passed and 1 failed. The following colleges were represented:

PASSED

College	Year Grad.	Per Cent
George Washington Univ. Med. School	(1929) 82.9, (1930)	87.2

Book Notices

Chronic Nasal Sinusitis and Its Relation to General Medicine: Based on the Author's Semon Lecture, University of London. The Toll of Nasal Focal Sepsis on Body and Mind. By Patrick Watson-Williams, Hon. Consulting Surgeon in Diseases of the Ear, Nose, and Throat, Bristol Royal Infirmary. Cloth. Price, $5. Pp. 221, with 109 illustrations. New York: William Wood & Company, 1930.

The author of this work is one of the best known English laryngologists who has contributed many excellent articles on rhinology and allied subjects. In this monograph much of the space is devoted to the subject of focal sepsis, or focal infections. Beginning with an historical survey of toxemia, bacteremia and selective affinities of organisms and toxins, the pathways of invasion, and the general symptoms and signs of focal sepsis, there is a discussion in considerable detail of complications involving the respiratory and intestinal tracts, the heart, the joints, the skin and the eyes. The author is more imbued with the firm belief that focal infection, or sepsis, as he terms it, is the cause of general conditions than is at present perhaps the tendency of physicians in America. Some years ago focal infections were used to explain the causation of almost every painful inflammatory condition in the body. The present enthusiasm regarding this is no longer so marked. The second part of the work deals with diagnostic measures, such as endorhinoscopy, transillumination and radiography. The author's main thesis is diagnostic exploratory suction of the nasal sinuses, the method he has employed for many years and on which he is able to base his diagnosis regarding the presence and the character of infections. Based on the results he has obtained, he has outlined his method of treatment. He advises and urges conservative measures, including diets and hygiene whenever possible. When operations are necessary, he prefers intranasal work at first. The illustrations are good, the author's style is clear, and the book is readable. One cannot perhaps quite agree with the author that definite focal infections are always present or give definite diagnostic signs in all cases; but since he is on the whole fairly conservative, the perusal of the monograph should be both interesting and instructive to rhinologists. Full credit is given in most instances to the many men who have studied the subject and contributed to the literature of chronic nasal sinusitis.

Experimentelle Bidrag til Spørgsmaalet om Hypophysens Livsvigtighed. Af Svend Felding, Reservelæge ved Frederiksberg Hospital. Paper. Pp. 120, with illustrations. Copenhagen: Levin & Munksgaard, 1929.

This is a thesis submitted as part of the requirements for the degree of doctor of medicine from the University of Copenhagen. In addition to discussing the anatomy and physiology of the hypophyseal region, the author stresses particularly the vital significance, as determined by extirpation and destruction, of the part of the tuber or infundibulum that forms the floor of the third ventricle. Within a period varying from a few hours to a few days after the removal of this part there develops in the dog apathy, somnolence, coma and death. The mechanism of death under these circumstances requires further investigation. The results described in this thesis may have a bearing on the methods and results of operations for hypophyseal and brain tumors.

Diathermy Medical and Surgical in Oto-Laryngology. By Dan McKenzie, M.D., F R.C.S.E., Consulting Surgeon, Central London Throat and Ear Hospital. Cloth. Price, $4. Pp. 184, with 23 illustrations. New York: Macmillan Company, 1930.

The first chapter of this monograph is devoted to the physics and mechanics of diathermy current and apparatus. The subject of medical diathermy is next discussed and emphasis is laid not merely on the indications but also on the contraindications to its use. In several sections the ear, nose and throat are considered in relation to treatments by means of medical diathermy It is refreshing to note that McKenzie is quite conservative in his statements regarding the benefits to be derived from the use of this measure in the various middle ear conditions. So many writers have been overenthusiastic with reference to the reduction of tinnitus and the improvement of hearing by means of diathermy that it is gratifying to note that the author does not make extravagant claims. Surgical diathermy is given considerable credit and deservedly so, since it has found extensive application in otolaryngology, particularly in the pharynx and larynx. In the removal of tonsils and especially stumps left over from previous operations, surgical diathermy has had rather wide use. Both in the benign and in the malignant diseases of the larynx it is considerably employed, and the methods are here described in detail, particularly with reference to destruction of malignant disease after laryngofissure. The last portion of the book is devoted to the treatment of ineradicable cancers. This work constitutes one of the volumes in the Anglo-French Library of Medical and Biological Science and should prove valuable to any one who desires a clear and sane exposition of diathermy and its relations to otolaryngology. The author writes in a lucid, succinct style, and the illustrations further clarify the subject.

Handbuch der Kindertuberkulose. Band II. Herausgegeben von Prof Dr Stefan Engel und Prof. Dr. Cl. Pirquet. Paper. Price, 120 marks. Pp. 887-1591, with 170 illustrations. Leipzig: Georg Thieme, 1930.

The first volume of this collection of monographs on the various phases of childhood tuberculosis was reviewed in The Journal, June 28. The articles contained in volume II maintain the general standard of excellence noted in the review of the first volume. Practically every phase of the subject receives careful and critical consideration. The scope of the volume is too extensive for detailed review. The contributors are for the most part renowned authorities in Germany and Austria, though French, American, Swedish and Swiss investigators have written for this volume. There is a chapter on tuberculin diagnosis with a consideration of reactions and their significance, and a discussion relating to the sensitization of the organism to tuberculin. Herbert Orel, who writes on this subject, states that it would be desirable to give every child a tuberculin test during early life so as to ascertain whether or not an infection has taken place.

In considering prognosis it is observed that, in view of the large number of children who are infected, a relatively small proportion succumb. Nevertheless, prognosis is obviously modified by a number of factors, among which are mentioned the virulence of the organism, the reaction of the infected individual, environmental influences, the state of nutrition, and economic conditions. While it is generally thought that the so-called occult tuberculosis presents a favorable prognosis, nevertheless it does not confer absolute immunity. Children thus infected are later on subject to superinfection and reinfection. It has been observed that some of these infected children develop a fatal, rapidly progressing form of pulmonary tuberculosis in the period from the fifteenth to the twentieth year of life. Childhood tuberculosis and phthisiogenesis are considered in relation to tuberculosis in later life. Behring's well known aphorism is stressed, to the refrain: "Adult phthisis is the end of the song which was begun in the cradle."

Prophylaxis receives the careful attention it deserves and is considered under the various divisions, prevention of exposure to infection, constitutional tendencies, and various forms and methods of active immunization. Nobel, who contributes the article on active immunization, concludes a thoughtful presentation of the subject by epitomizing our knowledge of tuberculosis immunization at the present time. He thinks that final judgment should be deferred because the whole question is still in the experimental stage. Nevertheless, "primum nil nocere" should be the first commandment in prophylaxis as well as in active treatment. The treatment of tuberculosis is discussed from every angle. The general treatment, the nutrition, the use of drugs in the treatment of symptoms, the value of sea climate, the mountain resorts, and surgical and orthopedic procedures are considered in interesting and detailed form. Tuberculin therapy also receives attention. The technic of administration, indications and contraindications are fully presented, and it is maintained that if the proper method is employed, the dosage carefully controlled and suitable cases selected, the treatment may help considerably and do no harm.

This volume completes the treatise on childhood tuberculosis. The work contains a wealth of material and is encyclopedic in character. Nothing seems to have escaped the attention of the editors and collaborators, and any one who is seeking information on any matter, new or old, relating to tuberculosis of childhood will find it contained in these volumes. The illustrious career of Pirquet began with his valuable contributions to the study of tuberculosis. Shortly following his death this monumental contribution of Engel and Pirquet was published and should serve as a fitting memorial to a great scientist.

Handbook of Therapeutics. By David Campbell, M.D., M.A., B.Sc, "Pollok" Lecturer in Materia Medica and Pharmacology in the University of Glasgow. Leatherette. Price, $4.50 net. Pp. 411, with 72 illustrations. New York: William Wood & Company, 1930.

That insufficiency in the teaching of therapeutics is an international calamity is indicated by testimony from Great Britain. In the preface, Campbell says: "The aim of the medical curriculum is to provide the student with sufficient knowledge to treat disease rationally; yet, as a rule, there is no part of his training with which the young graduate is more dissatisfied. He is taught pharmacology and therapeutics before he has had the opportunity of studying disease; he may even be instructed in therapeutics by one who, though possessing a medical degree, has not himself any experience of the practice of medicine. To some extent, no doubt, this is made good in the clinic, but it is too frequently the case that, when the history and physical signs have been elicited, the diagnosis, differential diagnosis, and prognosis discussed, and the pathologic aspect of the disease fully considered, the all important question of treatment is either ignored or is dealt with in such a perfunctory fashion that the student carries away no clear idea of the method of treating a similar case." The book includes chapters on the management of patients, the prescription, modes of administration of medicines, diet, water, heat and cold, climate and various other physical methods of treatment, the use of biologic products and the treatment of the various groups of diseases arranged in much the same way as in the ordinary textbook on the practice of medicine. Unfortunately, because of the large ground the author aims to cover, he does not go much deeper into therapy than most of these books on practice do, and he treats it in much the same manner. For these reasons, it hardly seems to present the ideal way of meeting the problem indicated by the author in his preface.

Refraction of the Human Eye and Methods of Estimating the Refraction Including a Section on the Fitting of Spectacles and Eye-Glasses. By James Thorington, A.M., M.D. Second edition. Cloth. Price, $3 net. Pp. 406, with 323 illustrations. Philadelphia: P. Blakiston's Son & Company, Inc., 1930.

In this well known book, all the tests applicable to various methods and instruments used in refraction are given in detail and well explained. The chapter on muscles deals chiefly with phorias, paralysis of the eye muscles being only enumerated. The author describes his own method of exercising ocular muscles. The book is a satisfactory outline of refraction and should be as well received as the first edition.

The Fourth Factor in the Etiology of Malaria: Its Relation with Anopheles and Its Particular Application to Malaria in Bengal. By Dr. P. C. Roy. Paper. Price, 5/-. Pp. 41. Bengal, 1930.

The author's somewhat startling thesis is that the basic etiologic factor in the occurrence of malaria is the presence of an aquatic plant, *Pistia* (called water-lettuce in English). He tries to show that in Bengal every area having this plant suffers from malaria and every area without it is free from the disease. Furthermore, he asserts that he has been able to control malaria by removing *Pistia* and to introduce the disease into new areas by introducing the plant. The basic cause of the relation of *Pistia* to malaria is supposed to lie in the fact that the plant contains many needle-like crystals which are eaten by *Anopheles* larvae and which so damage the gut wall that later when the adult feeds on infected human blood the ookinetes of *Plasmodium* can penetrate the stomach wall and infect the mosquito. Many obvious objections can be raised to the author's conclusions and hypotheses. In particular one wonders why the ookinetes of bird malaria, which are so similar to the human parasites, can penetrate the gut wall of the culicine mosquitoes without the advantage of the needles of *Pistia*. Besides scientific objections, the work is marred by its obvious polemic character in attempting to discount the work of established public health units.

Cancer of the Larynx. By Sir St. Clair Thomson, M.D., F.R.C.F., F.R.C.P., and Lionel Colledge, M.B., F.R.C.S., Surgeon to the Throat Department, St. George's Hospital. Cloth. Price, $7. Pp. 244, with 106 illustrations. New York: Macmillan Company, 1930.

This is an important work. Possibly no one can speak with more authority on the subject of cancer of the larynx than Sir St. Clair Thomson, who has devoted many years to careful, painstaking scientific work. The history and the frequency of laryngeal carcinoma, its pathology, signs and symptoms as well as the diagnosis and prognosis are discussed. One of the most important points is that with reference to the mobility of the vocal cords. It was thought for many years that one of the earliest signs of cancer involving the cords was an impairment of mobility. It is shown by Thomson and others and emphasized by him that this is erroneous and he has demonstrated that often it is a rather late symptom; therefore, a reliance on its early appearance often leads to mistakes in diagnosis until the disease is far advanced. With reference to the actual differential diagnosis the authors call attention to the fact that the most frequent error lies in mistaking laryngeal tuberculosis for carcinoma. It is interesting to note that the statement is made that the first laryngofissure for the removal of carcinoma of the larynx was carried out in America by Gurdon Buck in 1851. The technic of laryngofissure and laryngectomy is described in detail and the various methods are discussed critically. The last chapters of the book are concerned with pharyngotomy together with irradiation and palliative measures in the inoperable cases. As in most English papers and books, the style is clear, and the statements are made in a precise, logical manner. The book is well illustrated and is a valuable contribution. It should be in the hands of every laryngologist who desires to avail himself of the most recent conclusions. Seldom has so much important matter been included in so small a compass.

Radiologische Praktika: Band XII, Teil 1: Normale Anatomie des Kopfes im Röntgenbild [with English, French and Spanish texts]. Von Dr. Karl Goldhamer, Universitäts-Assistent. Paper. Price, 120 marks. Pp. 115, including 30 photographic plates, 30 illustrative schemas and 15 projection diagrams. Leipzig: Georg Thieme, 1930.

This atlas constitutes volume XII of the series of the Practical Treatises of Radiology covering the various portions of the body. Throughout the work from title page to the last plate, every statement is rendered in German, English, French and Spanish. In order that all possible information may be obtained, the films for the plates were made both from the living and from dead material. The plates are all negatives because, the author states, "it is negatives which are mostly used for diagnosis and because combining the interpretation of a negative seen in reflected light it is no doubt less difficult in combining the interpretation of a negative with that of the positive." It is difficult to describe the beauty of this volume. The pictures of the films are exceedingly clear, and on the lower portion of these plates made from the dried skull are sketches showing the exact position of the head with reference to the direction of the rays. Covering each plate is a celluloid leaf or sheet on which are traced in red the features depicted on the plate, together with numbers indicating the various anatomic points. On the opposite page are the legends for these numbers in the four languages. All together, this is a most sumptuous and splendidly .constructed work. If studied by rhinologists, otologists and head surgeons it will prove of immense profit to them. Both the authors and the publisher are to be heartily congratulated on this exquisite contribution to the literature of the anatomy of the head.

Practical Midwifery for Nurses. By Bethel Solomons, M.D., F.R.C.P.I., M.R.I.A., Master, Rotunda Hospital. Cloth. Price, $2.75. Pp. 354, with 136 illustrations. New York: Oxford University Press, 1930.

In Britain nurses are trained as midwives to attend women during pregnancy and in normal labor. This training includes experience in making vaginal examinations as well as external manipulations for diagnosis. Solomons' book, accordingly is much more explicit than American texts in describing the conduct of labor and detailed in just what the nurse-midwife may and may not be called on to do. It is in reality an abbreviated "Tweedy's" which Solomons edited in 1929 and which we reviewed most favorably in these columns a year ago. The text is well illustrated, the print large, and the paper of high grade. In the conduct of labor the nurse is warned to make as few vaginal examinations as possible and is advised to use the method of "external vaginal examination" for determining the progress of the presenting part. This is done by finger pressure in the area between the anus and the coccyx, externally. Apparently this maneuver, little known in this country, has proved satisfactory in midwifery. A splendid short introduction on nursing ethics opens the book; at the end is appended a chapter describing the "Rules of the Central Midwives Board," both of which will be read with profit by American nurses.

History of Haitian Medicine. By Robert P. Parsons, Lieut.-Com., M. C., U. S. N. Foreword by Edward R. Stitt, Rear Admiral, M. C., U. S. N. Cloth. Price, $2.25. Pp. 196, with 21 illustrations. New York: Paul B. Hoeber, 1930.

During the past few years, Haiti has become of great interest to the American public. Not only has the author added another chapter to the colorful history of the turbulent island, but he has outlined an achievement by the U. S. Navy Medical Department that reads like the brilliant work of Gorgas in Panama. Haitian medicine falls into three periods: the French colonial period during the seventeenth and eighteenth centuries, the more or less bizarre period of independence from 1804 to 1915, and the period of American occupation since 1915. The author considers these periods in succession together with enough general history to orient the reader. At the time of the American occupation almost all the inhabitants were affected with yaws, malaria and intestinal parasites, and, of these, yaws was by far the most important. The results of the fight against these infections are little short of marvelous. The final chapter on Haitian physicians is somewhat pessimistic, because the author, although pointing out their fine qualities and their high skill and ability, does not believe that they possess the administrative ability necessary to continue a successful national public health program after the withdrawal of American supervision. Throughout, the book reads like a novel and is to be recommended to all workers interested in preventive medicine.

Some Social Aspects of Mental Hygiene. Edited by Frankwood E. Williams, M D., Medical Director, National Committee for Mental Hygiene, New York City. Paper. Price, $1. Pp. 214. Concord, New Hampshire: The Annals of the American Academy of Political and Social Science, 1930.

This volume is essentially a symposium on the subject, covering the general aspects of mental hygiene in education and in mercantile life, and institutional treatment and community organization. The book is published as a part of the Annals of the American Academy of Political and Social Science. The essays are authoritative, interesting and thereby stimulating to workers in the field that they concern.

A Textbook of Hygiene. By J. R. Currie, M.A., M.D., D.P.H., Professor of Public Health in the University of Glasgow. Cloth. Price, $8.50. Pp. 844, with 110 illustrations. New York: William Wood & Company, 1930.

This volume covers the usual subjects found in textbooks on public health. It is excellently written and sufficiently complete. Its value from the standpoint of American workers is that it contains official acts relating to such subjects as milk, meat, disinfection, port administration, industrial hygiene, nurses' registration, and lodging houses. It is a pleasure to read this well bound, well printed and well illustrated volume.

Manual of Physiology for Students and Practitioners. By H Willoughby Lyle, M.D., B.S., F.R.C.S., Consulting Ophthalmic Surgeon to King's College Hospital, and David de Souza, Physician to Westminster Hospital and Lecturer on Medicine in the Medical School. Third edition Cloth. Price, $5.25. Pp 520, with 138 illustrations. New York Oxford University Press, 1930.

Although this book, because of its concise discussion, has many admirable points, it cannot be recommended to any class of students. Its section on endocrinology is antiquated. Collip's parathyroid extract is not even mentioned, although it has been well established as an important hormone by laboratory tests and clinical results for five or six years. Robertson's tethelin is mentioned, but the work of the past five years on the hypophysis and neighboring regions of the brain (Philip Smith, Evans, Kamm, Teel and others) seems to have completely escaped notice. One surely cannot condone such important omissions in a manual designed for students and practitioners.

Medicolegal

Skill Required of a Naturopath

(Hilgedorf v. Bertschinger (Ore.), 285, P. 819)

The plaintiff recovered a judgment in the circuit court, Multnomah County, against Bertschinger, a naturopath, for malpractice in performing an operation on her for menstrual irregularity and Bertschinger appealed to the Supreme Court of Oregon.

Although the defendant denied, said the Supreme Court, that he had performed an operation on the plaintiff and contended that he used instruments for inspection purposes only, there was ample evidence to take the case to the jury and the trial court committed no error in denying the defendant's motion for a directed verdict.

The defendant contended that a practitioner of the healing art is entitled to have the treatment of his patient tested by the rules and principles of the school of medicine to which he belongs. Consequently, he argued, it was error for the trial court to allow practitioners, other than naturopaths, to testify. It is true, said the court, that if a patient seeks to be treated by a naturopath, and such practitioner follows the methods usually employed by a naturopath, the practitioner is not negligent simply because a physician of another school would have treated the patient for that particular disease by some other method. Where, on the other hand, a naturopath in the treatment of a patient, uses surgical instruments and employs unsterilized lambs' wool for vaginal packing, as the testimony tended to show the defendant did in the present case, then such practitioner is working in the field where a regularly licensed physician and surgeon is qualified to testify. The court quoted from 21 R. C. L., pp. 383, 384 as follows:

> The rule which confines the inquiry as to a practitioner's skill and care to the rules and principles of the school of medicine to which he belongs does not, however, exclude the testimony of physicians of other schools or experts in other lines when that testimony bears on a point as to which the principles of the schools do or should concur, such as the dangers incident to the use of x-rays, or the existence of a condition that should be recognized by any physician, e. g., that the patient's hip joint was dislocated and not affected by disease. . . .

The trial court did not err, therefore, in permitting a physician and surgeon to testify concerning the condition in which he found the patient when he examined and operated on her and concerning whether or not, in his opinion, the treatment administered by the defendant was proper. In *Lehman* v. *Knott*, 100 Ore. 59, 70, 196 P. 476, the court said:

> *In a malpractice case the question whether a physician has in a given* case adopted the proper treatment is one in which the opinions of medical men may be received in evidence, and they may state whether in their opinion the treatment was proper or not, whether it was in conformity with the rules and practice of the profession. Rodgers on Expert Testimony (2d Ed.) § 64.

Finding no error in the record, the judgment of the trial court was affirmed.

Epilepsy and Workmen's Compensation

(Andrews v. L. & S. Amusement Corp. (N. Y.), 170 N. E. 506)

Andrews, while walking on a concrete sidewalk in the course of his employment, had an attack of epilepsy. He fell on the sidewalk and sustained a fatal fracture of the skull. The industrial board awarded compensation to his mother and the award was affirmed by the New York Supreme Court, appellate division. The employer and insurer appealed to the Court of Appeals of New York.

Apparently, said the court, the industrial board in awarding compensation, and the Supreme Court in affirming that award, regarded *Mausert* v. *Albany Builders' Supply Co.*, 250 N. Y. 21, 164 N. E. 729, as determinative. In that case the employee was a teamster and, during the course of his employment, he fell from the seat of his truck to the pavement and was fatally injured. It was held that his death arose out of his employment. The risk of falling from the seat of a truck was incident to and a risk of his employment. Such a risk would not surround him while sitting in a chair or while walking. Again, in *Barath* v. *Arnold Paint Co.*, 238 N. Y. 625, 144 N. E. 918, cited in the Mausert case, the injury resulted from a fall from a scaffold, due to an apoplectic stroke. It was held that the risk or danger was one arising out of the employment, because the loss of control through apoplexy while on a scaffold would result in a serious fall. The place of work increased the risk and danger from such an affliction.

None of these added risks or dangers, due to the employment, are found in the present case, the court said. The employee was walking on the sidewalk when he fell. The risk of falling to the pavement was not due to the employment. The same result might have followed if he had been coming to or going from his employment or if he had been in his own house. If the epileptic stroke itself had killed him there would be no recovery. Had the employee fallen from a ladder, from a scaffold or from a stairway, the chances of injury would have been increased. Had an accident caused his fall there would have been another element in the case, but there was no accident. He fell because of internal disorders, and the resulting injury was not due to any added risk of the employment. The court, therefore, reversed the order of the Supreme Court sustaining the award and dismissed the claim.

Two justices, in a dissenting opinion, said that subjection of the average person to an ordinary risk is no longer one of the tests for determining the question whether or not the injury arises out of the employment. The test is the relation of the services to the injury and of the employment to the risk. The risk need not be one peculiar to the employee nor one from which the general public is exempt. An injury received in the course of employment, said the dissenting justices, does not cease to be one arising out of the employment merely because some infirmity due to disease has originally set in action the final and proximate cause of the injury. A workman carries with him all his disabilities, and the fact that he has them does not destroy his right to compensation. The determining question is: Did the employment require the workman to be in the place where a floor or a walk or other structure caused his injury? The dissenting justices thought the award should be affirmed.

Hospitals: Charitable; Liability not Affected by Indemnity Insurance.—Hospitals administered solely for charity and which do not receive profit from their operation are not liable for the negligence of their physicians and servants, if due care and caution has been exercised in selecting them. An insurance policy issued to a charitable hospital contracting "to indemnify the assured . . . against loss from liability imposed by law upon the insured" indemnifies the hospital only for liability for negligence in its selection of physicians and servants. It creates no right of action either by the hospital or the patient therein against the insurance company, nor does it impose any additional liability on the hospital itself in favor of the patient. A patient may not recover damages, therefore, from a charitable hospital so insured, on an allegation that a roentgenogram of the patient's arm was so negligently taken in the hospital that it failed to disclose a fracture, where no negligence is shown in the selection of the physician who operated the x-ray machine.—*Mississippi Baptist Hospital v. Moore (Miss.), 126 So. 465.*

Society Proceedings

COMING MEETINGS

American Society for the Study of Disorders of Speech, Chicago, December 30-January 1. Dr. Sara M. Stinchfield, Mount Holyoke College, South Hadley, Mass., Secretary.

American Society of Tropical Medicine, Cleveland, December 27-30. Dr. Edwin Peterson, U. S. Naval Hospital, Washington, D. C., Secretary.

American Student Health Association, New York City, December 29-30. Dr. D. F. Smiley, Cornell University, Ithaca, N. Y., Secretary.

Society of American Bacteriologists, Boston, December 29-31. Dr. James M. Sherman, Cornell University, Ithaca, N. Y., Secretary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to The Journal in continental United States and Canada for a period of three days. Issues of periodicals are kept on file for a period of five years only. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending, but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

American Journal of Ophthalmology, Chicago

13: 943-1044 (Nov.) 1930

Pigmentary Degeneration of Retina in Cerebrospinal Syphilis. J. S. Friedenwald, Baltimore.—p. 943.
Eye Changes Observed in Paretic Patients After Treatment with Malaria. C. P. Clark, Indianapolis.—p. 946.
Influence of Pregnancy on Visual Field. J. P. Johns, Boston.—p. 956.
Posterior Lenticonus. R. I. Lloyd, New York.—p. 968.
Subtentorial Tumor: Case. C. T. Eber, St. Louis.—p. 974.
Sight-Saving Class Work. E. V. L. Brown, Chicago, and L. H. Carris, New York.—p. 983.
Krukenberg's Spindle. M. H. Post, St. Louis.—p. 987.
Sign in Differential Diagnosis of Lesions Producing Unilateral Exophthalmos. J. Wolff, New York.—p. 989.
Glaucoma from Apical Tooth Abscess. H. H. Levy, New York.—p. 991.
Table of Tonometer Readings. L. L. Mayer, Chicago.—p. 991.

American J. Roentgenol. & Rad. Therapy, New York

24: 349-476 (Oct.) 1930

Roentgenologic Diagnosis of Coarctation of Aorta (Adult Type). W. W. Fray, Rochester, N. Y.—p. 349.
*Amniography. T. O. Menees, J. D. Miller and L. E. Holly, Grand Rapids, Mich.—p. 363.
*Diagnosis of Early Ileocecal Tuberculosis. J. Gershon-Cohen, Philadelphia.—p. 367.
Normal Position of Patella. S. B. Boon-Itt, Bangkok, Siam.—p. 389.
*Results of Roentgen Therapy in 400 Cases of Goiter. G. E. Pfahler and J. H. Vastine, Philadelphia.—p. 395.
*Treatment of Carcinoma of Body of Uterus. W. Neill, Jr., Baltimore.—p. 412.
Detection, Estimation and Elimination of Radium in Living Persons Given Radium Chloride Internally. H. H. Barker, New York and H. Schlundt, Columbia, Mo.—p. 418.
*Thyroglossal Duct Cyst and Sinus. P. O. Snoke, Lancaster, Pa.—p. 424.
Syphilitic Infection of Lung: Case. H. J. Hutter, Hot Springs National Park, Ark.—p. 427.
Right-Sided Relaxation of Diaphragm: Case. H. Fritsch, Bielitz, Polen.—p. 430.

Amniography.—Obstetric roentgenography has been limited almost entirely to a demonstration of the fetal bones and uterine contour. Occasionally, when the subcutaneous fat of the fetus is unusually thick, the outline of an extremity is obtained. The slight difference in density of fat and liquor amnii is sufficient to cast a shadow. This suggested an artificial increase in density of the amniotic fluid to give contrast to fetal soft parts and placenta. Amniography is proposed by Menees et al. as a name for this procedure, differentiating it from uterography, the roentgenography of the nonpregnant uterus. This contrast is obtained by the injection of a 1 : 1 solution of strontium iodide through the anterior abdominal wall. The actual concentration is about 0.75 Gm. per cubic centimeter, as strontium iodide contains six molecules of water of crystallization. After the skin has been anesthetized with procaine hydrochloride, a small flexible lumbar puncture needle is passed into the amniotic cavity, usually below the umbilicus and near the median line. The puncture is made on the side with the fetal small parts. After fluid has been obtained through the needle, the injection is made slowly with frequent withdrawals of amniotic fluid to dilute the solution. Following injection, it is advisable to wait from half an hour to an hour before taking the films, to permit an even diffusion throughout the amniotic cavity. During this time the patient changes position frequently to assist in the mixing. The exposures are made on a Potter-Bucky diaphragm, a high milliamperage and relatively low voltage being used to insure a maximum contrast. The correct amount of solution to inject varies with the quantity of liquor amnii present and this is almost impossible to determine in advance If too much solution is injected, the whole interior of the uterus will become opaque and the object of the examination will be defeated. From 7.5 to 15 cc. of the solution has been used by the authors. The larger amounts caused too much opacity and probably 9 or 10 cc. will be sufficient for the average case in the latter months of pregnancy. In the twenty-one cases in which injection has been done there have been no injurious or toxic effects to the mother or fetus in normal pregnancies. In a case of placenta praevia at the sixth month, the fetus made a few feeble attempts at respiration. The placenta showed a partial separation. It was located low on the anterior wall and may have been perforated in the injection. The pulsating cord excluded any toxic effect to the fetus.

Diagnosis of Early Ileocecal Tuberculosis.—Ileocolography, with a double contrast air-barium enema, was employed by Gershon-Cohen in the study of ileocecal tuberculosis, in conjunction with and after a single contrast enema and an intermediary examination. These examinations were more valuable than either the single contrast enema or the serial roentgenographic studies of Brown and Sampson alone because they not only furnish an equivalent of the spasms, hyperperistalsis and hypermobility, anastalsis, with "filling defects," on which the diagnosis of early ileocecal tuberculosis is based in the serial examinations, but also manifest these equivalents earlier and more definitely. Many new phenomena are seen only in the double contrast roentgenograms, making possible a better concept of the tuberculous processes, their extent and intensity. The enema studies are self-sufficient in making the diagnosis in all stages of ileocecal tuberculosis, allowing checks to be made on all the observations. They are made with greater dispatch and less annoyance to the patient and require fewer exposures than the serial examinations.

Results of Roentgen Therapy in Goiter.—Observations made by Pfahler and Vastine and those of other roentgenologists in treating rather large series of cases of hyperthyroidism lead them to conclude that roentgen therapy offers as great prospects of cure or marked improvement as can be obtained by any other known means. In cases causing pressure or embarrassment of respiration, surgery is indicated. In nontoxic cases, they recommend surgical or medical treatment depending on the type. When medical treatment fails and surgery is refused in these nontoxic cases, several small series of treatments may be given, with little danger of impairment of the normal function of the gland.

Treatment of Carcinoma of Body of Uterus.—Taking all groups treated by Neill prior to five years ago, there were 109 cases; 76 patients have died—counting 6 patients lost sight of as dead—and 33 are living, making a total five year cure rate of 33 per cent. He says that, in operable carcinoma of the body of the uterus, radium offers a method of treatment comparable to surgery. It obviates the primary mortality and can be used safely in those presenting bad surgical risks. Radium offers the possibility of a cure and definite palliation in a number of inoperable and recurrent cases. When there is any doubt as to the extent of the disease, operation alone or combined with radium is the treatment of choice.

Thyroglossal Duct Cyst and Sinus.—A case of thyroglossal duct sinus is presented by Snoke in which the lateral anlage ducts are believed to have persisted rather than the usual median duct. Roentgen demonstration was made possible by the use of a ureteral catheter and iodized oil.

Chemical View of Pathogenesis of Tuberculosis.—Long feels that there is some reason for believing that the epithelioid cells of a tubercle, brought there through an allergic response, and increased in their hypersensitiveness by intimate contact with the developing micro-organism, may become increasingly incompatible chemically for the life of the bacillus within their protoplasm.

Intracerebral Method of Inoculating Guinea-Pigs for Diagnosis of Tuberculosis.—An experimental study was made by Magath and Feldman in an attempt to evaluate the reliability of the method of intracerebral injection in determining positive tuberculous infection from clinical material that was negative to careful microscopic examinations. The material consisted of 211 specimens, representing 153 persons. For the purpose of comparison, use was made of the results obtained in the guinea-pigs that had been given routine subcutaneous and intraperitoneal injection with portions of the same material. Nearly three times as many positive results were revealed by the routine method as by the intracerebral method. The difference was probably not due to the intracerebral exposure being a less sensitive one. It could perhaps be accounted for by the difference in the amount of infective material possible to inject in the two groups of animals. Also, however, the result could have been due to the large number of animals given intracerebral injection which died before a demonstrable tuberculous infection had had time to develop; this factor constitutes the most serious objection to the use of the intracerebral method for determining tuberculous infections of clinical origin. Although the method might be of value as an auxiliary procedure in selected cases, it cannot be offered as the method of preference in the diagnosis of tuberculosis by inoculation of animals. It has, however, unquestionable merit as a means of inducing the disease in certain studies on experimental tuberculosis. Injection of one guinea-pig subcutaneously and of another intraperitoneally, with suspected tuberculous material, makes a satisfactory routine method in tests for this disease in which animals are used.

Complement Fixation Test in Tuberculosis.—The results obtained in the complement fixation test in 668 active cases of tuberculosis, in 20 inactive, and in 314 nontuberculous cases are reviewed by Wadsworth et al. Approximately half were in clinics or sanatoriums; the remainder were patients of physicians in general practice. The results obtained in these routine examinations are of especial interest when compared with the series previously published, which consisted only of cases that were as accurately diagnosed as the modern methods of hospital practice permitted. In the former series, fixation of complement was obtained with the tubercle antigens in from 85 to 95 per cent of the tuberculous cases; in the present series in 84.9 per cent. There were, however, a number of well advanced cases with tubercle bacilli in the sputum and certain incipient cases with a low grade of activity in which no reactions were obtained. Fixation occurred in only a comparatively small proportion of the serum from cases diagnosed as inactive or apparently cured. Reactions in the group of nontuberculous cases of this series were obtained in 14 per cent, as compared with 13.6 per cent in the previous series. In both instances these percentages included the cases reacting in the complement fixation test for syphilis. In this series all the reactions in nontuberculous cases were of low grade (± or +); marked fixation (2+ or stronger) was obtained only in tuberculous cases. In general the degree of activity in the serum was proportional to the activity of the process, or, to state it more accurately, proportional to the reactivity of the tissues in the process, suggesting that a detailed study of individual cases and accurate titration of the activity of the serum from time to time might provide data of broad diagnostic or prognostic significance.

*Use of Sodium Ricinoleate in Bacterial Hypersensitiveness of Intestinal Tract. R. S. Morris and S. E. Dorst, Cincinnati.—p. 396.

Phrenicectomy and Intercostal Neurectomy for Pulmonary Tuberculosis.—Alexander recommends this operation, with the reservation that his clinical experience with it is based on only six cases, as an apparently effective substitute for thoracoplasty in those cases in which there is no very large cavity demanding mechanical closure but in which considerabl reduction of respiratory mobility, together with some retractio of the thoracic wall, is desired.

Thoracoplasty in Treatment of Pulmonary Tubercu losis.—Brown regards thoracoplasty as an aid to nature' method in closing cavities when its success is threatened b seemingly insurmountable difficulties, size of cavity, its bein held open by extensive adhesions, the recurrence of large hem orrhages, and the failure of lesser efforts to help.

Diagnosis of Tubercle by Caulfeild's Inhibitive an T C F Reactions.—As a result of twenty years' clinical obse vations with 5,000 different cases and 25,000 double serolog tests in a group of five clinicians, Ogden believes that Cau feild's inhibitive and the T C F are laboratory aids in t recognition of latent tuberculosis in the adult. These tests i the adult are comparable in value to the universally accepte intracutaneous tuberculin test as diagnostic in infants. The most dramatic value is seen in tuberculosis contacts. By mea of positive tests he has diagnosed latent tuberculosis two yea before clinical disease and one year before even demonstrab by roentgen ray. The incubation period in the adult is fro one to five years.

Problem of Syphilis in Tuberculosis Clinic.—Gre calls attention to the possibly greater prevalence of syphilis tuberculous patients than is generally acknowledged. He inve tigated 1,944 cases. The Wassermann reaction was positi in 12.4 per cent. The cases were checked by roentgenolog examination of the lungs, repeated sputum analyses, and t complement fixation test for syphilis. The tests were ma on patients applying at a clinic for diseases of the chest, w usually presented the symptoms of cough, loss of weight, afte noon fever and weakness.

Sodium Ricinoleate in Bacterial Hypersensitiveness Intestinal Tract.—Five-grain (0.3 Gm.) globules of sodiu ricinoleate three times a day before meals (and often a four at bedtime), were administered by Morris and Dorst to group of seventy patients. All other forms of treatment, su as diet and colonic flushings, were omitted, to avoid confusi in the interpretation of results. In patients with mucous coliti the effect was striking. In addition to relieving them su jectively, there was a noticeable decrease in the mucus in t stools and finally an absence. Anorexia, loss of weight a belching were often favorably influenced. There was not infr quently a gradual gain in weight, with a feeling of well bei and relief from the dyspeptic symptoms. The patients we able to play golf or carry out exercises that fatigued the formerly. In this group of seventy patients, thirty were entire relieved of their symptoms. In the forty patients remainin the majority experienced great relief, though not entirely r of symptoms. In the cases of mucous colitis, it has been ne essary to use the ricinoleate capsules indefinitely, and in a patients of this group there is a great tendency to recurren of symptoms.

Evidence Shown in Roentgenograms of Changes in Vascular Tree Following Experimental Sympathetic Ganglionectomy. B. T. Horton and W. McK. Craig, Rochester, Minn.—p. 698.

Operative Treatment of Lesions of Lower Extremities in Diabetes Mellitus.—Two hundred and eighty-one operations for lesions of the lower extremities in patients with diabetes mellitus form the basis of this report by McKittrick and Pratt. These lesions are classified into (1) those due to arterial insufficiency and (2) those due primarily to infection. The importance of such a classification is demonstrated by the results obtained. *Staphylococcus albus* has proved of great importance in operations on diabetic patients. It is the organism most frequently found in cases of minor sepsis of the feet and may be the cause of fatal septicemia. Gas bacillus infection following amputation for gangrene has been a rare complication in this series. Production of gas in wounds infected by staphylococci and streptococci has been frequently seen. The passive exercises of Buerger have proved the most satisfactory method of stimulating circulation. Indications for the various types of operation done are discussed. The 281 operations represent 231 separate conditions with a mortality of 11.6 per cent. The mortality in 119 major amputations for conditions primarily due to arterial insufficiency was 17.6 per cent, and in 19 amputations for conditions primarily due to infection was 10.5 per cent, a combined mortality of 16.6 per cent. These patients died of the surgical conditions. Spinal anesthesia has been the anesthesia of choice.

Spinal Anesthesia in Near East.—Harrison regards spinal anesthesia as the procedure of choice for surgeons working in the jungle, as well as for those in large centers.

Etiology of Neoplasms of Breast.—Clinical observations collected by Taylor from the literature and a study of 271 cases indicate that etiologically the tumors of the breast, including carcinoma, are closely related to those of the endometrium, thyroid and ovary, are somewhat allied to myomas of the uterus, and are in a way equivalent to tumors of the prostate. The tumors of these five organs, therefore, form a group the etiology of whose members shows many points of mutual resemblance. To attempt to relate inflammatory accidents of lactation to cancer of the breast is to classify it etiologically with cancer of the cervix, which on both inductive and deductive grounds appears unjustifiable.

Induced Paralysis of Diaphragm.—Yates and Raine assert that induced paralysis of the diaphragm is beneficial to patients suffering from a number of pleuropulmonary diseases. It makes thoracotomy and thoracoplasty simpler and safer. Its greatest value, prophylaxis, is attained by early utilization. Experimental and clinical evidence indicates a more frequent, more extended and earlier employment of this minor procedure, but always in conjunction with other measures.

Experimental Healing of Bone After Parathyroidectomy.—The lack of calcification of the bones after experimental fracture, in conjunction with the low blood calcium, led Speed and Rider to infer that the calcium stream is directed away from the bones after parathyroidectomy, and that parathyroidectomy, either through this change of calcium stream or balance or through some still undiscovered factor, delays the healing of fracture in experimental dogs.

Effects of Hemorrhage Under Ether Anesthesia and Spinal Anesthesia.—The study made by Burch et al. to determine the effects of loss of blood under ether anesthesia and under spinal anesthesia led to the conclusion that the danger of circulatory failure from hemorrhage is greater under spinal anesthesia than under ether anesthesia.

*Effect of Ingestion of Potassium Iodide on Electrocardiogram of Normal Individuals. D. McEachern and B. M. Baker, Jr., Baltimore.—p. 304.

Origin of Miliary Aneurysms of Superficial Cerebral Arteries.—In the course of a study of a group of cases of miliary aneurysms of the cerebral arteries, Forbus has found a hitherto undescribed peculiarity in the structure of the wall of the arteries, on which it would appear that the formation of miliary aneurysms depends. This peculiarity consists in a muscular defect in the media located in the portion of the vessel wall forming the angle of bifurcation. This medial defect was sought for in arteries other than those of the brain and found to be present in cases in which there were no aneurysms. Such defects were noted, for example, in the coronary and mesenteric arteries. The frequency of occurrence of the medial defect in normal as well as pathologic cases was found to be sufficiently great to indicate that the peculiarity in structure at the point of bifurcation is a relatively normal arrangement. It seems justifiable to say that miliary aneurysms of the superficial cerebral arteries and most probably those of all other arteries of medium size occur quite independently of any inflammatory process, arteriosclerosis or external trauma, and that these aneurysms as such are not congenital malformations. That they are acquired lesions arising from a combination of focal weakness in the vessel wall, resulting from a congenital muscularis defect, and degeneration of the internal elastic membrane, due to continued overstretching of this membrane, seems the most logical conclusion.

Mechanism of Wassermann and Precipitation Tests for Syphilis.—Eagle asserts that there is not merely a superficial similarity between the flocculation tests for syphilis and bacterial agglutination by an antiserum, or between the Bordet-Gengou phenomenon (specific complement fixation) and the Wassermann test. The analogy extends to the basic mechanism of the reactions. Reagin, an altered globulin in syphilitic serum, combines with the colloidal particles of beef heart lipoid ("antigen"). The surface film of protein thus formed sensitizes the particles to flocculation by electrolyte (Sachs-Georgi, Kahn and others), and also adsorbs complement (Wassermann). Antibody-globulin affects bacteria, red cells or foreign protein in exactly the same manner. The serum change characteristic of syphilis may therefore well represent an antibody response to products of infection. As will be shown, the fact that normal tissue lipoids can be used instead of spirochetes as the antigen in the test tube reaction does not exclude this possibility.

Potassium Iodide and the Pulse Rate.—A statistical analysis was made by McEachern of the pulse rates of thirty-four patients, without thyroid disease or other interfering circumstances, to whom potassium iodide had been administered. Following administration of the drug, twelve showed a significant increase in pulse rate and five a significant decrease. These changes came on gradually about the third to the seventh day and reached a maximum at about the tenth day. The rate returned to normal within a week or so after the drug was discontinued.

Potassium Iodide and the Normal Electrocardiogram.—Iodine, in the form of potassium iodide, was administered by McEachern and Baker by mouth to fourteen normal members of the hospital staff each day in doses of 1 Gm. daily during the first week, 2 Gm. daily during the second week, and 3 Gm. daily during the third week. Four of the subjects were forced to drop out because of rather severe iodide reactions. The remaining ten took the drug for periods ranging up to twenty-two days. Compound solution of iodine was used for the first few days but gave way to potassium iodide owing to bitter complaints of the recipients. In this connection it is suggested that enthusiasts for large doses of compound solution of iodine try a short course of the drug themselves. Electrocardiographic records were made before administration of the drug and every five days thereafter till the end of the experiment. No significant effect on the electrocardiogram was noted.

Influence of Epinephrine on Growth of Carcinoma and Sarcoma.—The toxic action of epinephrine on the Flexner-Jobling rat carcinoma and the Rous chicken sarcoma has been investigated by Sugiura and Benedict in three different ways; namely, (*a*) injection directly into and around the tumor, (*b*) injection subcutaneously at a point away from the tumor, and (*c*) in vitro. The development of small tumors in animals is completely inhibited by repeated intratumoral injections of epinephrine while large tumors are seldom beneficially affected by repeated injections. The repeated subcutaneous injection of epinephrine at a remote point does not affect the growth of rat carcinoma and chicken sarcoma. In vitro experiments indicate that the proliferating capacity of the Flexner-Jobling rat carcinoma was partially destroyed by epinephrine, but the Rous chicken sarcoma was unaffected as respects its growth after implantation. Hence, any possible therapeutic value of epinephrine for cancer treatment is limited to local application.

Potassium Content of Skeletal Muscle.—Pilcher et al. found that the water content of pieces of gastrocnemius muscle removed by biopsy from patients with cardiac edema was invariably increased. The percentage of solids was correspondingly decreased. These changes usually persisted after clinical signs of edema had disappeared. The potassium content of the wet muscle from edematous patients was invariably abnormally low. The amount of potassium in the dry muscle was usually but not always diminished. As edema decreased, the potassium content of the wet muscle rose in three subjects; that of the dry muscle increased in two of them. The administration of potassium dibasic phosphate was followed by a rise in the potassium content of the muscle.

Action of Histamine on Pancreas.—The action of histamine on the pancreatic secretions into the duodenum in children of different ages has been investigated by Neale and Klumpp. Histamine caused no increase of either the volume of pancreatic secretion or its enzyme activity. An increase in the alkalinity of the duodenal contents (alkaline tide) accompanied the secretion of acid into the stomach in response to histamine.

Urea Nitrogen Content of Cutaneous and Venous Blood.—The concentration of urea nitrogen in the blood from ear puncture has been compared by Johnston with that from the vein in thirteen experiments on six normal and six nephritic subjects, without regard to food intake. No difference between venous and cutaneous blood exceeding the limit of experimental error was found to exist.

Sympathetic Inhibition of Large Intestine in Hirschsprung's Disease.—A most important desideratum in surgery of the sympathetic nervous system is the development of accurate criteria for detecting sympathetic overactivity in the various systems affected. The temporary interruption of sympathetic stimuli to the involved area is used to select appropriate cases and to estimate how much effect removal of sympathetic innervation will have. Spinal anesthesia has produced temporarily motor activity of the colon in two cases of Hirschsprung's disease reported by Scott and Morton and in experiments made by them on animals. The motor anomaly in at least one type of megalocolon is dependent on central sympathetic inhibition of the large bowel. They propose the effect of spinal anesthesia on the motor function of the large bowel as a test of sympathetic overactivity in Hirschsprung's disease.

Treatment of Lobar Pneumonia with Homologous Convalescent Serum.—Two patients with type II lobar pneumonia and one patient with type III lobar pneumonia were treated by Beebe and Sutliff with serum from homologous donors. The serum was all given intravenously within forty-eight hours, on the third and fourth days of the disease, and in amounts varying from 310 to 440 cc. One patient with type II pneumonia recovered after having the usual eight days' course, whereas the other two patients became progressively worse and died following treatment. In spite of the attempt to administer such convalescent serum under favorable conditions, the results obtained in these three cases fail to demonstrate any benefit derived from its use.

Constipation and Catharsis.—Jordan distinguishes between the sluggish colon that lacks sufficient stimulus to work and the fatigued, weakened colon that lacks the power to propel its contents and has lost the coordination characteristic of normal. The patient with a sluggish colon usually gives a history of infrequent, dry stools, without abdominal distress or digestive symptoms. The patient with the fatigued, weakened colon usually gives a history of stools of variable consistency, from the hard dry type to the watery or mushy type. He complains of shifting abdominal distress, distention and eructations, for which he has used cathartics in increasing doses, supplementing them with the use of coarse food and enemas. The treatment of these two types of constipation should be different. The former requires only the inclusion in the diet of such foods as will stimulate the colon, such as fruit, vegetables and coarse flours. General hygienic measures and exercise are also to be recommended. In the treatment of the second type, rest—both general and local—should be the keynote. Bed rest and even hospitalization are often required. Rest for the colon itself is obtained by the use of diet, at first relatively low in residue and nonirritating, physically and chemically. Heat, applied externally and used in the form of hot drinks and food, is useful for its soothing effect. Atropine is of value in many cases. As the colon gradually recovers from its fatigue and irritation, as evidenced by the subsidence of distress and digestive symptoms, and by its improvement in function, the diet is gradually enlarged until only the most irritating foods, such as raw fruits, the coarser vegetables, fried foods and pastries, are excluded. During this period of rest, and before the function of the colon is restored, bowel movements are induced by procedures that produce the least irritation, such as small oil or saline enemas. Laxatives are entirely discarded during the period of reeducation of the colon.

Inception of Acute Leukemia.—A case of acute myeloid leukemia in a man, aged 20, is reported by Milhorat in which the leukemic blood picture developed in a period of six days. The course was rapidly downhill. On the fifty-third day after his admission, and the thirty-seventh day after the appearance of a leukemic blood picture, the patient died. Permission for a necropsy was not granted.

Treatment of Fractures of Humerus by Mobilization and Traction.—The apparatus used by Coonse and Moore consists of a Thomas or Jones-Murray humerus splint to which is attached a flexible forearm piece (Pierson attachment). This splint is suspended from an overhead frame or bar. Traction is applied in the line of the humerus by means of rubber bands or a weight suspended over a pulley. Traction straps are also applied to the forearm and maintained by means of a Spanish windlass. The forearm attachment is then counterbalanced to allow active and passive motion of the elbow joint. The humerus splint is so suspended that a moderate amount of active and passive motion of the shoulder can be maintained. The method is said to be ideal for treatment of uncomplicated fractures of the humerus in healthy adults. It prevents the occurrence of joint adhesions and joint stiffness. It promotes increased circulation to the injured part with consequent rapidity of callus formation and repair of the fracture. It prevents atrophy of the muscles. The method also affords the great advantage of visibility and palpability of the injured part. Any marked displacement in alinement is readily visible. It is also possible with this method to correct existing deformity. Lateral displacement can be controlled by direct pressure on the part and anteroposterior displacement by elevation or depression of the forearm. It is also possible to administer massage and baking as desired. Economically there is a tremendous saving to the individual, as the period of disability has been greatly shortened. This method is not applicable to old people who would not tolerate bed treatment or in the case of young children. The method requires careful hospital supervision.

Nosebleed and Vomiting in Rheumatic Individuals.—The frequency of spells of nausea, vomiting (cyclic vomiting) and epistaxis was ascertained by Levine et al. in 100 individuals suffering from rheumatic fever or one of its allied conditions, such as chorea or rheumatic heart disease. This was compared with the frequency of similar symptoms in a control group of 100 nonrheumatic individuals of approximately the same age, coming to a surgical clinic. According to the method used in estimating the occurrence of these symptoms, they were found to be from three to four times as frequent in the rheumatic as in the nonrheumatic group.

Larynx as Related to Surgery of Thyroid.—Since Kocher called attention to the possibility of injury to the superior laryngeal nerve in thyroid surgery, and since all observations point to the fact that the interarytenoid muscle is supplied by the internal branch of the superior laryngeal nerve, and since his dissections indicate that it is easy to injure the superior laryngeal nerve in the ligature of the superior thyroid artery, Nordland feels that it is reasonable to conclude that postoperative disturbance to the voice may occur from injury to this nerve in thyroid surgery. Further, because the recurrent laryngeal nerves occur anterior to the inferior thyroid arteries just as frequently on both sides, and because they penetrate the thyroid space a little farther from the tracheo-esophageal groove than is usually described, therefore, to avoid injury to these nerves, extrafascial ligation of the inferior thyroid artery, according to de Quervain, is more reasonable when ligation of this artery is contemplated.

Calcium Partition in Pregnancy, Parturition and **Toxemias.**—Cantarow et al. assert that during the course of normal pregnancy and early labor there is a gradual diminution of total serum calcium, a slight increase in diffusible calcium, and a marked decrease in nondiffusible calcium. The ratio of diffusible to nondiffusible calcium increases steadily, reaching a maximum in the first stage of labor. This disturbance is identical with that present in bronchial asthma and allied disorders. The toxemias of pregnancy are characterized by a marked decrease in the ratio of diffusible to nondiffusible calcium, due in most instances to an increase in the nondiffusible fraction. This finding suggests a condition of diminished cell permeability with associated disturbance of tissue functions in these disorders.

Aschheim-Zondek Reaction for Pregnancy.—A study of the Aschheim-Zondek reaction in 100 cases has convinced Mack that it offers a reliable laboratory method for the early diagnosis of uninterrupted intra-uterine and extra-uterine pregnancy, hydatidiform mole, and malignant chorio-epithelioma. Its simplicity permits it to be carried out without elaborate equipment. It has been proved a valuable adjunct to ordinary clinical methods in difficult problems involving the diagnosis of pregnancy.

Resection of Presacral Nerve in Treatment of Cord Bladder.—A case of cord bladder is described by Learmonth and Braasch in which both pelvic and pudic nerves were partly paralyzed. An operation is described by which the thoracicolumbar sympathetic supply to the bladder was interrupted. In view of the part played by this operation in eliminating residual urine, the possibility is raised that the hypogastric nerves carry inhibitory influences to the bladder.

Morbidity and Mortality Following Pelvic Surgery.—In a series of 1,000 consecutive gynecologic operative cases reviewed by Dannreuther, there were complications during convalescence in 79, a morbidity of 7.9 per cent; 19 patients died, a mortality of 1.9 per cent. He concludes: Postoperative transfusion should never be necessary except in the presence of ectopic pregnancy, secondary hemorrhage or sepsis. Preoperative cystoscopy and renal function tests will eliminate many useless pelvic operations. Severe anemia, pyorrhea, respiratory disorders, a compromised myocardium, arterial hypertension, and impaired metabolism are indications for postponing operation in elective cases; spinal anesthesia may reduce the hazards in emergency cases. Irradiation and diathermy are dangerous in the presence of active infection or necrobiosis. Meticulous peritonealization and burying all suture knots minimizes the likelihood of postoperative intestinal obstruction. The incidence of pulmonary complications can be lessened by the invariable employment of a skilled anesthetist. Correcting indicanuria and obstinate constipation before operation will practically eliminate postoperative pyelitis. Persuading the patient to practice active motion of the extremities throughout convalescence is good insurance against thrombophlebitis and embolism. Pronounced tachycardia developing during the first half hour of anesthesia is an indication to terminate the operation as soon as possible. Unpreventable surgical shock will develop occasionally in profoundly septic patients. Patients with a high metabolic rate should not be subjected to irradiation. The control of postoperative morbidity and mortality following gynecologic operations is contingent on conscientious preoperative preparation of the patient, expert anesthesia, sound surgical judgment, and skilful after-treatment.

Reading of Results with Kahn Test in Tinted or Cloudy Serum.—A technic has been devised by Levine to facilitate the reading of Kahn results in hemolyzed and highly tinted serum and in serum of doubtful reaction. A quantity of the serum, usually 1 cc., is placed in a tall serologic tube, and a wax pencil mark is made to indicate the meniscus of the fluid. Two parts of saline solution (in this instance 2 cc.) are now added to the tube, and the contents well mixed. The tube now contains three volumes (3 cc.) of fluid. To this are added two parts (2 cc. in this case) of a saturated solution of ammonium sulphate, and the contents of the tube are shaken. The tube is now centrifugated at high speed (about 3,000 revolutions per minute) for fifteen minutes. The precipitate must become well packed at the bottom of the tube. The supernatant fluid is then thoroughly drained and saline solution added to the wax-pencil mark, thus bringing the contents of the tube to the original volume of the serum (1 cc.). The tube is shaken until the entire precipitate is dissolved. It is again centrifugated to remove all extraneous suspended matter and the clear fluid is poured into another tube and used in the precipitation test, which is conducted in exactly the same manner as prescribed by Kahn for serum (5). That is, into each of three Kahn tubes antigen-saline mixture is placed in 0.05, 0.025, and 0.0125 cc. quantities; then to each of the tubes are added 0.15 cc. of the clear and colorless fluid containing the dissolved precipitate. The tubes are shaken for three minutes; 1, 0.5, and 0.5 cc. of saline solution are added, respectively; the tubes are again shaken for a short time and the results are read. Highly tinted serum is rendered practically colorless, and chylous and turbid serum becomes clear. Bile-stained serum is cleared of extraneous substances which might cause confusion in the end-results. Doubtful reactions occasionally change in their intensity to become stronger or slightly weaker, but are clear-cut wherever the precipitate is the result of interplay of immunologic factors. The procedure is in accord with the Kahn test in every respect.

Coincident Carcinoma, Tularemia and Syphilis.—Minehart relates the case of a man, aged 39, who, while driving his car, ran over a large jack rabbit. Soon afterward one of the front tires went flat and he got out to change tires. While removing the old tire he noticed that it was well covered with rabbit hair and blood. Incidentally, while changing the tire he suffered an abrasion on his left foot. This he examined and applied a temporary dressing. He remained in his usual health for a week or ten days and then became quite ill, with malaise, chills, fever and severe headaches. Also the abrasion on his left foot showed signs of irritation. His blood serum was positive for tularemia. He remained in the hospital for about four months, when he was discharged, improved. In a few days, however, he became seriously ill again. His blood was again examined. The result of the Wassermann test was 100 per cent positive for syphilis and negative for *Bacterium tularense*. Despite intensive treatment, the patient succumbed. At the necropsy, among other things, an infiltrating new growth was found about the right kidney. This proved to be hypernephroma, primary, in the right suprarenal, with metastases to the liver and lungs; another example of a cancer unsuspected before death.

Paroxysmal Auricular Fibrillation.—Hollingsworth reports a case of repeated attacks of paroxysmal auricular fibrillation, with normal rhythm recurring promptly each time under quinidine, and the attacks practically abolished under 0.2 Gm. doses, twice daily. There subsequently developed nocturnal epileptiform seizures with cardiac mechanism at the time undetermined, these seizures being practically abolished following administration of barium chloride. The patient is in good general condition and is leading a normal life five years after the initial trouble began.

Treatment of Bronchiectasis with Iodized Oil.—Stiehm reports his results with iodized oil in these cases. Complete cessation of symptoms occurred in 33 per cent; improvement in 46 per cent; no improvement in 21 per cent. Complete credit for the results is given to the insufflations of iodized oil. Hygienic living, postural drainage, rest, and the systemic effect from the iodine content of the iodized oil are all given consideration. Case histories show that patients treated with iodized oil do better than those without treatment.

Pathology of Congenital Torticollis.—Middleton contends that in all cases "congenital" torticollis results from fibrosis in the sternomastoid muscle consequent on the development and absorption of the so-called sternomastoid tumor of infancy. Sternomastoid tumor and, therefore, torticollis, result from a temporary acute venous obstruction in the muscle, this obstruction taking place during labor. It is probable that such a temporary venous obstruction has been rendered permanent by patchy intravascular clotting in the obstructed venous tree. Attention is drawn to the frequent occurrence of an exostosis at the clavicular attachment of the sternomastoid muscle in cases of fibrosis affecting that head. The facial asymmetry and plagiocephaly associated with torticollis is shown to be dependent on the prolongation of the cervical curve into the base of the skull and is therefore properly called a scoliosis capitis. An explanation is given of the etiology of idiopathic facial asymmetry and plagiocephaly of infants.

Anatomic Result of Periarterial Sympathectomy.—The condition of the nerves in the main arteries was investigated by Blair et al. in a leg amputated five weeks after the periarterial injection of alcohol into the sheath of the femoral artery. All nerves running with the artery at the seat of the previous operation appeared to have degenerated distally, but an abundant additional supply running to the vessels lower down from the ordinary nerves of the limb then showed up in marked contrast. This accessory nerve supply arrives on the vessels of the leg mainly in the popliteal space. The incidence of these accessory nerves was also checked by anatomic dissection in another limb. The incoming nerve twigs have a characteristic structure, being composed chiefly of small medullated fibers, with a few large medullated fibers and a fair number of nonmedullated fibers. It is suggested that these incoming nerves may be especially concerned with the blood vessels to the muscles.

Purpura as Acute Abdominal Emergency.—Bailey reports two cases in which subserosal extravasation of blood as a manifestation of purpura constituted an acute abdominal emergency. In one of the cases about four feet of jejunum was the color of bright-red blood and on closer examination extravasated blood could be seen beneath the serosa. The whole of this area was heavy with blood. No intussusception or obstruction was found. In the second case the patient complained of acute abdominal pain, spasmodic in character; he had vomited copiously and repeatedly. One year previously he had had a similar attack lasting three days. Preparatory to an abdominal examination, while the nurse adjusted the bedclothes, the patient grasped the bedrail above his head, and in so doing exposed a large bruise on his arm. An examination of the limbs showed a typical purpuric rash. Deep tenderness in the epigastrium was the only physical sign on abdominal examination. The rectal examination was negative. The diagnosis of purpura with submucosal hemorrhage into the jejunum was made, and it was resolved to open the abdomen if the symptoms continued. As it happened, the abdominal pain and vomiting subsided within an hour, and in a fortnight the rash had faded almost completely. Some months later the patient was again admitted with similar symptoms, and he stated that attacks of colic and vomiting had recurred at weekly intervals. As the platelet count was low, after three weeks' rest in bed the spleen was removed after preliminary blood transfusion. Ten months later the patient wrote that he had been quite free from colic and was at work, although the rash appeared if he allowed himself to become constipated.

Mixed Tumors of Salivary Glands.—The pathologic material from fifty-two cases of mixed tumors of the salivary glands and a certain number of fresh tumors were examined by Patey. He concludes from this study that the mixed tumors of the salivary glands are a composite group of epithelial tumors, the varying pathologic features of which depend on the degree of differentiation attained, the rapidity of division of the cells, and the amount of myxomatous change undergone by the epithelium. According to the degree to which these changes have taken place, all gradations may be encountered between a myxoma on the one hand and a highly differentiated tumor with ducts and acini on the other, and between a slowly growing tumor with regular cells and an irregular anaplastic growth. Based on these factors, a practical pathologic classification has been evolved. The combined pathologic and clinical study has shown that this classification allows of a certain amount of correlation between the clinical and pathologic observations but that the correlation is by no means complete.

Operation for Complete Exposure of Elbow Joint.—Molesworth describes an operation which he says is easily executed in practice and will prove of service in a search for loose bodies and fragments of bone. Repair of T-shaped and other articular fractures will be facilitated and arthroplasty with preservation of the strong lateral ligaments may be expected to yield a stable joint. He also says that it lends itself to the exposure of those complicated injuries involving bone, joint and nerves encountered in this situation.

Hemangioma of Kidney.—A case is reported by Mackey in which dangerous hematuria arose from a cavernous hemangioma of the renal pelvis. Seventeen examples of hemangioma of the kidney have been collected from the literature. The material has been classified and an attempt has been made to correlate symptoms with the situation and pathologic characters of the lesions. The treatment of the various lesions is briefly considered.

Sarcoma and Trauma.—Willan reports a case of spindle-cell sarcoma of the femur associated with an undoubted injury to the same area. Roentgenograms showed a normal bone three months after the accident; within the next five months there was a spontaneous fracture from the growth. Similar growths were found in two other bones. Death took place one year and eleven months after the accident. Sarcoma was confirmed by a postmortem examination.

Cardiac Failure in Persons with Angular Deformity of Spine.—Coombs reports four cases in which there was a gross deformity of the dorsal spine. In three, there was an angular kyphosis of tuberculous origin. In the other, angulation was lateral as well as anteroposterior and was said to have occurred in another member of the family, in association with symptoms of cardiac failure, like those which the patient experienced. All these four subjects had been deformed for many years; three of them since early childhood; but not until a few months before death—twelve months in one case, less than six months in the others—were there any cardiac symptoms. In all, the first complaint was of dyspnea, and this increased rapidly until it reached an extreme degree. By the time that Coombs saw them, all four were cyanosed, and in one patient the fingers were clubbed and purple. In all of them there was an extreme and increasing dropsy up to the waist line. The pulse was quick but regular in every instance; the blood pressure was low and the pulse pressure gap narrow in three of the four patients. Unfortunately no electrocardiograms were taken, as all four patients were extremely ill when first seen. Alternation of the pulse was not detected in any of them. The physical signs were so distorted by the deformity of the chest that not much could be definitely established. It is, however, worthy of note that the impulse was always diffuse and the basic second sound relatively loud, while in all a "bruit de galop" was heard. Physical signs of bronchitis, amounting in one instance to a bronchopneumonia, were also observed. Postmortem examinations were made in two cases. In one patient, a globular enlargement of the heart was noted, in which both ventricles shared, the wall of the right chamber being as thick as that of the left. Neither pericardium nor valves showed any gross change. This is true also of the heart in the second case. Here was noted a remarkably acute angulation of the aortic arch, which had been thus penalized for clinging too faithfully to the deformed spine. In this case also there was some fibrosis round the root of the pulmonary artery, as well as a manifest reduction in the capacity of the lungs.

Atypical Meningitis.—Micks describes three cases of meningitis in which the cerebrospinal fluid, though turbid with polymorphonuclears, did not contain any organism visible in films or producing growth on standard culture mediums. In two of the three, recovery took place; in the third the meningitis seemed nearly cured when sudden death took place. Micks suggests the possibility of sporadic infections with a filter-passing organism of the same type and habits as the virus which is believed by many to be the cause of the myelitis which occasionally follows other fevers, for example, vaccinia and measles.

Occult Nephritis and Relation to Pregnancy Toxemias.—Browne and Dodds bring forward experimental evidence to show that chronic renal damage may exist during the intervals between pregnancies and yet fail to give clinical indication of its presence. In these cases, the subjects of occult nephritis, albuminuria appears toward the end of pregnancy. The albuminuria need not necessarily appear at an earlier date and may even appear at a later date, in successive pregnancies. These observations suggest that in the so-called recurrent toxemias of pregnancy there is all the while a mild degree of chronic renal damage, which undergoes exacerbation under the strain of pregnancy, and that the "low reserve kidney" may be in the same category.

Leukorrhea in Virgin.—Sharman points out that there is encountered in virgins a definite, clinical condition of profuse leukorrhea, unassociated with anemia, debility and constipation, which, in them, are the common factors associated with mild and varying degrees of "white discharge." Almost two thirds of all cases occur between 20 and 30 years of age: most are unassociated with dysmenorrhea or any other complaint. A follow-up involving seventy-six inpatients shows that the results of hospital treatment have been unsatisfactory. Numerous conditions may be causes or, at least, associated factors, although in many cases no definite cause is apparent. Anemia, constipation and tuberculosis are not etiologic factors. A "congenital erosion" is often unaccompanied by leukorrhea and the latter may be quite unrelieved, when an erosion, its presumed cause, is excised or otherwise "cured." Leukorrhea, varying in profuseness from time to time and associated with prolonged intervals of amenorrhea (or scanty menstruation) and iliac pain or backache, is sometimes encountered in cases of endocrine imbalance of the ovarian or thyro-ovarian type. Fungus infections of the vagina—thrush and yeast—are commoner than is generally believed. Although no case of *Trichmonas vaginalis* vaginitis was encountered by Sharman, he says that the possibility of the presence of the causative parasite in virgins should be borne in mind. A careful evaluation of the history must be made. The patient should be examined under anesthesia; a vaginal fresh-drop (in physiologic solution of sodium chloride) and bacteriologic smears and cultures from the vagina, cervix and uterine cavity should be taken and examined carefully as they may be the source of excessive discharge: this may save unnecessary dilation of the cervix or other intervention. Indiscriminate douching is condemned, not only because it is painful, objectionable and difficult in the virgin, unless a special nozzle or catheter is used, but also because it is almost valueless as a therapeutic measure. The almost routine use of dilation and curettage of the uterus, in an attempt to cure virginal leukorrhea is to be deprecated. On the basis of a thorough and methodical examination of the case, appropriate treatment should rest.

Death of Child Following Induction of Labor with Quinine.—Sadler et al. state that when three doses of quinine (10 grains, or 0.65 Gm.) are given at hourly intervals the peak of urinary excretion and, therefore, probably the maximal concentration in the blood of the mother lies usually between the sixth and twelfth hour after the first dose: there is evidence that wider spacing of the dosage is not advantageous. Quinine is readily excreted into the placenta (1 : 66,000) and liquor amnii (1 : 10,000); it has been found in fetal tissues in strengths (1 : 50,000-1 : 100,000) capable of toxic effect and after intervals that suggest that maternal reabsorption from the fetus is slow and that fetal urinary excretion (1 : 6,000) is limited. Cumulation of quinine in fetal tissues can occur. The presence of meconium in the liquor amnii is more frequent after quinine but there is no evidence that quinine is a stimulant to fetal intestinal muscle; histologic facts suggest intra-uterine asphyxia as a probable cause. Quinine induction does not predispose to postnatal jaundice or defective growth in the infant. From experiments with isolated mammalian uteri they have found that quinine is less reliable as a stimulant in nonpregnant than in pregnant uteri, and even in the latter its action is not constant. Wide variations in time occur between the administration of quinine and the onset of labor. They are of the opinion, from clinical evidence, that quinine is not of any value to induce labor except in fully mature or postmature cases but that in such cases and when labor has commenced it does accelerate and strengthen the uterine contractions, without the risk of causing contraction of the cervix. Although there is experimental evidence to prove that quinine may cause intra-uterine death of the child, statistics show that this risk is not greater than that of stillbirths from undiscovered causes in otherwise normal labors. Postmortem examinations on many of the still-born children following quinine induction showed intracranial injuries. This suggests that there was a mechanical difficulty in delivery and emphasizes the great care necessary in selecting induction of labor as a means of treatment but does not condemn the quinine method of induction.

Blood Sedimentation Test in Gynecology.—One hundred and thirteen cases were examined by Jackson at various stages of pregnancy. Twenty-five were at the second or third month, and of these only one showed an increased sedimentation rate. Of the remaining eighty-eight cases in the later months, only five showed a sedimentation rate of 20 per cent or under after two hours, all the rest being definitely increased. Apparently after the formation of the placenta, certain factors, be they changes in the protein content of the blood, the cholesterol content or the circulation of hormones, come into play which alter the physical and chemical properties of the blood and thereby increase sedimentation. These factors are more evident as pregnancy advances, for, broadly speaking, the sedimentation rate increases with the age of the pregnancy. This may have some bearing on the question of the toxemias of pregnancy, though Jackson has not found the sedimentation rate to be more rapid in cases of albuminuria than in normal cases at the same stage of pregnancy. He has had only one case of eclampsia, and in that patient there was no undue increase in the rate, although in eclampsia the globulin and fibrinogen content of the blood is said to be raised. The one rapid sedimentation rate in this group was in a case of severe pyelitis at the seventh month, with a swinging temperature, in which an inflammatory condition was superimposed on the pregnancy. Thirty-four cases of extra-uterine pregnancy occurred in the series. Twenty-four cases showed only a slightly increased sedimentation rate; ten showed an increased rate. Of these, two cases showed the sac to be definitely infected (confirmed microscopically), two patients had an old-standing pelvic hematocele with adhesions and considerable irritation of the peritoneum, and one patient had a pelvic peritonitis at operation, and her convalescence ran a most disturbed course for some days, until she discharged pus freely by the vagina, after which she slowly improved. Of 220 cases of pelvic inflammation, fifty-eight had a normal sedimentation rate on admission: of these, twenty-three were mild cases of pelvic inflammatory mischief which required merely local medication or some minor manipulation. The remaining thirty-five quiescent cases were treated by means of laparotomy. Among these, nineteen patients had conservative operations, in which the uterus, with the whole or part of the adnexa, was retained. In the remaining cases, the pelvic organs were removed by total or subtotal hysterectomy. Only one of this group had any postoperative complication, this being merely a mild sepsis of the wound. One hundred and sixty-two cases of acute and subacute lesions were investigated. Eighty-eight cases were treated purely conservatively, sixty-seven of which had a "rapid" or "very rapid" sedimentation. There were twenty cases of pelvic cellulitis, of which seventeen came in the "very rapid" group. The results in these eighty-eight cases justified the adoption of conservative methods. In sixty-one cases, the sedimentation rate settled down steadily and the symptoms completely subsided. Five cases required colpotomy for the evacuation of pus, and improved thereafter. Sixteen cases improved as regards symptoms, but the sedimentation rate did not settle to any great extent, though when some of these cases were seen later, the rate was found to be nearing normal limits. Four patients were dismissed improved, but returned later with a recurrence of symptoms, and the sedimentation rate being suitable, underwent operation. Two cases did not improve. Taking the results together, of thirteen patients operated on with a sedimentation rate of over 30 per cent, nine gave trouble after operation, whereas, in the large group of sixty-one cases operated on with a sedimentation rate of under 30 per cent, only four caused any anxiety. Forty-three cases of ovarian cysts were investigated, including three cases of simple fibroma. Thirty-eight of these, of which eight were cases of torsion of the pedicle, had a sedimentation rate within normal limits; viz., from 8 to 19 per cent in two hours. Four patients had an increased rate. Of these, one was found to have an infected adherent friable cyst. A second had a large abdominal swelling tender to palpation—the sedimentation rate was so rapid (59 per cent in two hours) that operation was delayed. The third patient was found to have free hemorrhagic fluid in the peritoneal cavity, foul-smelling and obviously infected with coliform organisms. The ovarian cyst had ruptured, only a little fluid remaining within its cavity. Its wall was necrotic, and the peritoneum and cyst wall were acutely infected. The fourth case was a fibroma of the ovary. The sedimentation rate was rapid. The patient died on the following day, and postmortem examination confirmed the presence of a twisted fibroma. The cause of death, however, was a bilateral lobar pneumonia, which was in the stage of gray hepatization. Fifty-two cases of fibroids were examined, and the results are comparable with the observations in the ovarian cyst group. In cases of carcinoma of the cervix, the sedimentation rate does not appear to be of any great practical value.

Cancer of Bladder: Treatment by High Frequency Current with Open Bladder.—Boeckel describes fourteen cases of cancer of the bladder in which he used etincelage with open bladder. All the patients suffered from hematuria, most of them from cystitis also. In all the cases a cystoscopy revealed a large sessile or infiltrated tumor in various localizations; the immediate operative results were excellent; disappearance of hemorrhages and pain was always effected. The after-effects were more varied. One patient died a month later from embolism; another died eighteen months later of an apoplectic stroke; a third died after eight months from cancerous cachexia. Three of the others were treated too recently to be considered at this time. All of the eight remaining patients are in excellent health, although in a few cases a later cystoscopy revealed a small tumor that was cured by electrocoagulation. Boeckel feels justified, therefore, in advocating etincelage with open bladder as the operation of choice in the treatment of cancer of the bladder in which the tumor is too large to permit of endoscopic electrocoagulation. The method employed is as follows: Under general anesthesia a large cystostomy is made and good retractors, preferably of the Legueu type, are introduced into the bladder so that the smallest details of the vesical cavity are visible. The exuberant portions of the neoplasm are trimmed with curved scissors, usually without the application of forceps or ligatures. Then the high frequency current is used, first electrocoagulation then etincelage with powerful sparks to the large base of the tumor. All the suspected points and all bleeding areas are then sparked. The wound in the bladder is drawn together with several catgut sutures and a Marion drain is left in the cavity. Lavage of the bladder with silver nitrate is performed every day. The Marion drain is not replaced by an indwelling urethral catheter until the urine becomes clear, which usually requires a longer time than after a prostatectomy.

Case of Pulmonary Abscess from Staphylococcus Aureus in Nursling. P. Lereboullet, M. Lelong and F. Benoist.—p. 1284.
*Meningeal Spirochetosis of Hydric Origin: Digital Contamination. J. Troisier and Y. Boquien.—p. 1298.
*Syndrome of Agranulocytosis and Septicemia from Meningococci in a Child of Ten Years. Railliet and Ginsbourg.—p. 1318.
*Pulmonary Gangrene Cured by Tracheal Injections of Iodized Poppy-Seed Oil. H. Eschbach.—p. 1324.

Meningeal Spirochetosis from Digital Injury.—Troisier and Boquien report a case of meningeal spirochetosis in a man, aged 26, a dishwasher in a restaurant. His finger was accidentally pierced by a fishbone, which permitted infection of the hand by the polluted water in which he was forced to work. The spirochetal virus reached the epitrochlear lymph node by means of the lymphatic passages and produced a septicemia with involvement of the meninges, a marked herpetic reaction and inflammation of the anterior portion of the eye. The cerebrospinal fluid as well as the blood showed first a predominance of polymorphonuclears and then a content almost completely lymphocytal. In spite of the marked symptoms of acute meningitis, the disease remained benign. One mild relapse occurred. The virus was eliminated through the urine. The spirochetal origin of the infection was proved both by serodiagnosis and by inoculation of guinea-pigs with the urine of the patient.

Agranulocytosis and Septicemia from Meningococci in a Child.—Railliet and Ginsbourg report the case of a girl, aged 10 years, in whom they observed at first a mild and apyretic purpura accompanied by an ulceration of the buccal mucosa. Later a double hemorrhagic and infectious syndrome appeared. Analysis of the blood from the time fever appeared revealed an anemia with leukopenia and agranulocytosis and at the same time a septicemia that was found to be caused by meningococcus C. The child died after eleven days. With the hemorrhagic symptoms present in this case the syndrome was identical with the syndrome of secondary infectious agranulocytosis described by Aubertin and that of the pure agranulocytosis of Schultz: sex, severe infectious condition at the beginning, ulceronecrotic lesions of the buccopharyngeal mucosa, jaundice, leukopenia with agranulocytosis, fatal evolution in a short time, noticeable enlargement of the hematopoietic organs and marked modifications of the blood cells. The authors believe this case worthy of mention because of the fact that the organism isolated was a meningococcus, whereas earlier cases of this type were caused by *Staphylococcus aureus* or by various streptococci.

Pulmonary Gangrene Cured by Tracheal Injections of Iodized Poppy-Seed Oil.—Eschbach describes two cases of gangrenous pulmonary abscess in which a cure was effected by several intratracheal injections of iodized poppy-seed oil, the first consisting of 15 cc. of the oil and later ones of 20 cc. One patient had already been given antigangrene serum in subcutaneous injections when the iodized poppy-seed oil was administered, but the serum had not produced amelioration. Since surgical intervention in such cases is difficult and dangerous, the author feels that injections of iodized poppy-seed oil should be tried before an operation is performed.

*Cholesterol and Bilirubin Contents of Blood of Mother and Child. H. Hinglais and J. Govaerts.—p. 137.

Cholesterol and Bilirubin Contents of Blood of Mother and Child.—Hinglais and Govaerts conducted a series of experiments to determine the dosage and relationships of maternal and fetal cholesteremia and bilirubinemia. They found that although hypercholesteremia in the mother is frequent at term it is by no means a constant phenomenon. They observed a distinctly low cholesterol content of the blood in infants at birth. Although the hypothesis of placental origin of a part of the fetal cholesterol cannot entirely be eliminated, nevertheless the excess of cholesterol in the fetal suprarenals indicates an endogenous source of at least a part of the cholesterol. No direct relationship was found to exist between the maternal hypocholesteremia and the need of the fetus for cholesterol. The excess of cholesterol in the mother is valuable, however, because of its antitoxic and antihemolytic qualities. During the first few days after birth, the infant shows a rapid and marked augmentation of the cholesterol content of the blood. This seems at least partly due to the activity of the suprarenals. Moreover, it was observed that the cholesteremia increased more rapidly when absorption of the vernix caseosa was allowed than when the vernix caseosa was immediately removed by washing. The authors found no basis, however, for the hypothesis of an amniotic origin of the cholesterol of the vernix caseosa. No direct relation was found to exist between the excess of bilirubin in the blood at birth and the low cholesterol content. It was noted, however, that the bilirubinemia, which is the result of hemolytic processes, decreased during the first few days after birth. This is undoubtedly due to the fact that the increased cholesteremia exerts an antihemolytic influence that checks the production of bilirubin. The authors also noted that the bilirubinemia decreased more rapidly in the infants whose vernix caseosa was absorbed and in whom a more rapid augmentation of cholesteremia was observed.

Double Joint Fixation in Therapy of Sacrocoxalgia. G. Pieri.—p. 361.
Associated Traumatisms of Spleen and Left Kidney. P. Goinard.—p. 372.

Arterial Encephalography in Diagnosis of Cerebral Tumors.—Pinto describes the method of arterial encephalography introduced by Egas Moniz, which he believes deserves an important place among methods of observation for diagnosis and localization of cerebral tumors. The method is wholly inoffensive; even the attacks of jacksonian epilepsy that follow the injection are now avoided by the administration of phenobarbital in the preparation of the patient. The after-effects of the operation are never unpleasant and are often beneficial. This method of diagnosis often gives particularly definite results, as in the case of tumors of the temporal lobes which cerebral arteriographs reveal by showing marked displacements toward the top of the sylvian group, often accompanied by obliteration of the carotid sulcus. Frontal tumors are shown by curvature of the carotid sulcus and lowering of the initial portion of the sylvian group, and occipital tumors by the evident displacement of the terminal branches of the sylvian group or by the alteration of the circulation in that part of the brain.

*Influence of Ablation of Sympathetic Ganglions on Evolution of Different Forms of Cutaneous Grafts. W. Dobrzaniecki.—p. 537.
Mechanism of Action of Venous Ligatures in Arterial Obliterations. R. Leriche and R. Fontaine.—p. 602.

Ablation of Sympathetic Ganglions and Evolution of Cutaneous Grafts.—Dobrzaniecki describes a series of experiments on male rabbits from 6 months to 1 year of age in which he observed the influence of ablation of the superior cervical ganglion on different forms of autologous and homologous cutaneous grafts. The terrain innervated by this ganglion includes only one side of the head. The grafts were made from two to three days after the ablation of the ganglion because of the excessive transudation and lymphorrhea that occur immediately after the intervention. For the transplantations the experimenters used free grafts of skin, pedicled grafts of skin, dermo-epidermic grafts and injections of suspension of epithelium in physiologic solution of sodium chloride. In all cases both autologous and homologous grafts were used. Free autotransplantation of skin, on the sympathectomized side of the head, produced an edema of the matrix and the graft and an abundant exudation at the edge of the graft, which allowed it to become mobile and to become entirely fused with the surrounding skin. A marked hyperplastic reaction in the epidermis and a neoformation of connective tissue set in immediately, with the result that in a few days the line of implantation was only slightly marked. On the nonsympathectomized side necrosis was produced, exudation was slight, and the graft became dry and thin and adhered to the base. Foreign body granulomas appeared and after twenty-four days the graft was still markedly distinguishable from the matrix. With dermo-epidermic autografts, on the sympathectomized side a cyanosis appeared during the first two or three days. After from five to seven days the cyanosis disappeared and small necrotic patches were observed. About the eighth day microscopic examination revealed a marked desquamation of the surface epithelium and the vessels were dilated and turgescent. On the nonsympathectomized side heavy losses in the grafts were produced, with leukocytic infiltration in the graft and destructive and necrotic lesions of the matrix. Autotransplantation of pedicled skin produced practically the same results as were obtained with free transplantation of skin. Homotransplantation proved a distinct failure with all kinds of grafts. During the first three days the appearance of homografts was identical with that of autografts, but after four or five days necrosis appeared, with degeneration of the epithelial cells. Injection of auto-epithelium produced cicatrization by proliferation of the cells of the papillary layer injected, which was shown macroscopically by the appearance of small epithelial islands at the surface. The cicatrization was much more rapid on the sympathectomized side. Injection of homo-epithelium proved as great a failure as homotransplantation of skin. In addition to the experiments with grafts, autologous and homologous cells were injected between two layers of skin of an intact ear, thus producing a culture of epithelial tissue. The autocells were much better tolerated by the organism than the homocells, the latter producing marked alterations in the blood vessels and connective tissue.

A Lateral Route for Anesthesia of Semilunar Ganglions. A. Defrise.—p. 899.
Humerus Varus. A. Nicotra.—p. 914.

Primary Sarcoma of Duodenum.—Soli says of the treatment of primary sarcoma of the duodenum: Drugs have not given any results to speak of. Radium and roentgen rays may be used only after surgical intervention, to act on the regional lymph nodes, which are sometimes the point of departure of a recurrence though macroscopically they may appear unaffected. Surgery is the only thing that, thus far, has given satisfactory results, for, if intervention is early and the diseased portion of the duodenum is widely resected, a permanent cure can be expected. Although surgery, in recent years, has made enormous progress in dealing with a duodenal sarcoma, it is often obliged to confine itself to palliative treatment, since, owing to the fact that the disease is not especially painful, the patient is not usually seen until the tumor is inoperable. There are, however, a few patients who, being in the habit of noting even slight disorders of the organism, present themselves to the surgeon in time and recount a history of fitful dyspepsia, slight loss of weight and general weakness. If the clinical and roentgen examination do not give precise results and the patient, in spite of suitable medical care, shows no improvement, an exploratory laparotomy is advisable, which, while harmless, may sometimes save a patient from certain death. When the diagnosis is reached in time, operative intervention is indicated and the technic varies with the location of the tumor. In the supra-ampullar forms, a resection is done, as in cancer of the pylorus, according to Billroth I or II, Polya, or otherwise. In the periampullar forms, the curative problem is more difficult and the prognosis is less favorable. When the development of the tumor makes it necessary to resect a portion of the duodenum, one may have recourse to pyloric exclusion, posterior gastro-enterostomy, cholecystogastrostomy or cholecysto-enterostomy, and implantation of the pancreatic duct in the small intestine. This operation is grave and is nearly always followed by death. The subampullar forms, if they are circumscribed, may be treated by resection and successive suture of the wall; but, if the neoplasm has invaded a certain extent of the duodenum, the same technic is recommended as for the diffuse periampullar forms. In the grave cases with inoperable stenosis the sole treatment is gastro-enterostomy.

*Active Immunization of the New-Born and Nurslings Against Diphtheria. E. Schwarz.—p. 977.
*Affinity Between Measles and Whooping Cough. V. Mikulowski.—p. 984.
Landry's Acute Ascending Paralysis. G. Cuomo.—p. 1005.

Immunization of the New-Born and Nurslings Against Diphtheria.—Schwarz attempted to produce active immunization against diphtheria in two groups of infants. The first group comprised fifteen nurslings aged from 11 months to 2 years to whom three injections of diphtheria toxoid in doses of 0.5, 1 and 1.5 cc., were given. The second injection was given seven days after the first, and the third injection was given two weeks after the second one. The second group comprised ten new-born infants aged from 6 days to 6 months. These received two injections of 0.5 cc. each of the toxin-antitoxin floccules recommended by Schmidt. It has been observed that these doses provoke the formation of the desired antitoxin in the blood of infants aged more than 6 months. The second injection in this group was given seven days after the first. The condition of immunity of infants in both groups was tested before the treatment and fifteen days after the last injection, both by means of the Schick test and by the direct determination of the antitoxin in the blood serum by the intradermal injection of the blood serum to be tested into guinea-pigs. Infants younger than 6 months failed to produce antitoxin. They cannot be considered as protected against diphtheria by active immunization. When they are in danger of contagion, passive immunization should be resorted to, though the protection which it confers is transient. The author believes that the organism before reaching the age of 6 months is in a condition of specific inertia which prevents any reaction to diphtheria antigens with the consequent inability to provoke the formation of diphtheria antitoxin. The organism, however, is able to react with the production of other types of antibodies (though in moderate amounts) after the injection of vaccines other than diphtheria. The provocation of active immunity was more successful in nurslings aged more than 6 months. The production of antitoxin was obtained but at a low concentration.

Affinity Between Measles and Whooping Cough.—Mikulowski states that there is a prophylactic, epidemiologic and clinical affinity between measles and whooping cough. The complication of these diseases causes a high mortality in children aged less than 5 years. During epidemics of measles, the aggravation of pulmonary symptoms in children who have had whooping cough should be considered as caused by measles and the child should be isolated. If the pulmonary disease was so serious that the child died before manifesting clinical symptoms of measles, death should also be considered as caused by measles in a period of incubation, which had not time to appear clinically and had only caused a sudden aggravation of the pulmonary symptoms. Children who were in contact with the patient should be isolated as carefully as if it were a proved case of measles. In nurseries, homes for children, schools and other centers for children, strict care should be taken to avoid contact between children with measles and other children, but especially with those who have had whooping cough. Measles, even in its most attenuated form, causes grave recurrences of whooping cough and the development of new pneumonic foci at the site of the old lesions. For this reason the author does not favor vaccination with immunizing serum against measles among children who have had whooping cough, with the aim to provoke immunity during epidemics. When immunization is indicated in those children, it is advisable to resort to passive (though transient) immunization by means of the serum of convalescents.

Policlinico, Rome

Torsion Spasm and Occupational Poisoning Due to Carbon Disulphide. G. Quarelli.—p. 413.
Automatism Reflexes in Upper Limbs and Effects of Irradiation. G. Vercelli.—p. 427.
*Tuberculoma of Left Cerebellar Hemisphere. E. Jacarelli.—p. 434.
*Meningeal Hemorrhage. P. Berri.—p. 442.

Tuberculoma of Left Cerebellar Hemisphere.—Jacarelli describes a case of tuberculoma of the left cerebellar hemisphere in which the clinical syndrome, with few general symptoms (choked disk, headache), was characterized by disturbances of equilibrium of the cerebellar type, with a slight motor deficit to the left intermittent nystagmus and severe and early mental disturbances. The necropsy revealed, in addition to hydrocephalus of moderate intensity, a large tuberculoma with peculiar histologic features, surrounded by a vast area of softening, localized in the left cerebellar hemisphere. In the absence of signs of notable cerebral hypertension, the author holds that the grave psychic phenomena, rare in tumors of the cerebellum, were of toxic origin, and due to the absorption of toxins originating in the large necrotic tuberculous focus.

Meningeal Hemorrhage.—Berri describes a case of subarachnoid hemorrhage of the algic type, which developed in a man, aged 31, affected with bronchial asthma, following an injection of an epinephrine preparation, which had provoked an intense reaction of an epinephrine type. It is probable that the hypertensive drug, having penetrated the circulation directly, provoked hyperemia and stasis in the meningo-encephalic vascular region and acted as an occasional cause on a vascular terrain that was abnormally sensitive, owing to constitutional and acquired factors.

Acute Pancreatitis. G. Lucchese.—p. 1309.
*Acute Gastric Ectasia: Case. F. Stipa.—p. 1316.
*Insulin Treatment in Athrepsia in Infants. D. Amici.—p. 1318.

Acute Gastric Ectasia.—Stipa reports a case of acute gastric dilatation. He discusses the etiology and pathogenesis of the disorder and interprets his case as due to a probable paresis from superingestion of food.

Insulin Treatment in Athrepsia in Infants.—Amici describes two cases of athrepsia—one due to gastro-enteritis and the other to unsuitable diet and gastro-intestinal dyspepsia—in patients aged respectively 14 and 4 months. In both cases the beneficent action of insulin was evident not only from the notable increase in weight secured in a short time but also from the rapid improvement in the general condition, and also from the stimulative influence on the appetite and the general activity, which was especially evident in the second case, in which the young patient had fallen into a state of grave vital depression.

37: 1345-1376 (Sept. 15) 1930. Practical Section

Ratio of Oxyhemoglobin to Hemoglobin in Some Types of Anemia. G. Lega.—p. 1345.
*Physical Sign in Seropneumothorax. M. Mazzetti.—p. 1348.
*Fractures Resulting from Traumatic Crushing of Acetabulum with Intrapelvic Luxation of Head of Femur. E. Truzzi.—p. 1352.

Physical Sign in Seropneumothorax.—Mazzetti describes a physical phenomenon not reported before, which consists of a characteristic sound, similar to that produced by percussion on a closed or slightly open cavity, on a leather bottle partially filled with some liquid, or on the stomach of a person with aerophagia, after dinner. The sound is heard while percussion is made along the posterior axillary line and on the scapular line with the aim of determining the level of liquid in the pleural cavity in cases of seropneumothorax. The point of major intensity of the sound is about a fingerbreadth above the level of the fluid. When percussion is made below or above that point, the sound diminishes gradually until it disappears completely when percussion is made either in the portion of the pleural cavity filled with the effusion or in the portion filled with air. The author believes that percussion made at the level of the fluid transmits to its surface vibrations from the thoracic wall, which incite numerous waves of small amplitude on the surface of the fluid. The waves give the metallic tympanism that characterizes the sound. Certain conditions of the thoracic wall as well as of the pleural cavity are necessary in order to produce the sound. Among conditions related to the pleural cavity are the following: The fluid contained in the pleural cavity should be of low density, its amount must be proportional to the volume of air, and the intrapleural pressure must not be less than zero.

Fractures Resulting from Traumatic Crushing of Acetabulum with Intrapelvic Luxation of Head of Femur.—Truzzi makes reference to a particular type of fracture that results from traumatic crushing of the acetabulum, with intrapelvic luxation of the head of the femur. This type of fracture has been known under several different names. Early diagnosis and treatment are important. Both the symptoms and the roentgenograms clearly indicate the presence of such a fracture. On rectal examination the head of the femur is felt inside the pelvis. Passive movements of the leg cause pain and displacement of the head. Roentgen examination gives valuable information. The author explains the arrangement of some dark and light areas seen in the roentgenograms, which are characteristic of the two subtypes of that fracture (the fracture either with partial or with total dislocation of the head of the femur into the pelvis). The author makes reference to the various bloodless and surgical methods used in the treatment of this fracture. He reports a case, in a patient, aged 42, in whom he obtained good results by the application under anesthesia of progressive longitudinal traction on the joint, while on the thigh a traction transverse to the direction of the femur was applied. After combined longitudinal and transverse traction was made, the joint was placed in a cast for some time. When the patient was observed one year after the operation, he showed a complete functional cure.

He can now walk up stairs without a cane. The movements of the joint are normal and he has only a slight limitation of the movements of abduction and of extension, a slight claudication while walking, and a shortening of 0.5 cm. in the leg.

*Is There a Hormone of the Spleen? P. Tremonti.—p. 1383.
Sodium 2-Oxo-5-Iodo-Pyridine-N-Acetate in Blood Following Intravenous Injections. R. Ascoli.—p. 1394.
Hemorrhagic Diathesis and Blood Coagulation. A. Fieschi.—p. 1396.

Is There a Hormone of the Spleen?—Tremonti concludes: The spleen secretes, under normal conditions, a substance that is constantly demonstrable in the splenic blood through its characteristic action on biologic preparations. He thinks that the splenic substance is identifiable with acetylcholine. The acetylcholine normally secreted by the spleen may be interpreted as a splenic hormone, taking the conception of hormone given by Gley. The splenic hormone participates, in all probability, in the regulation of the mechanism of the blood flow through an action that is intimately associated with the epinephrine present in the blood.

*Anticolibacillary Serotherapy: Its Principal Applications in Medicine and Surgery. H. Vincent.—p. 1423.
Changes in Cardiovascular Apparatus in Intoxication Due to Carbon Disulphide. G. Pennetti.—p. 1427.

Anticolibacillary Serotherapy: Its Principal Applications in Medicine and Surgery.—Vincent points out the great diversity of pathologic conditions that may be due to *Bacillus coli* as an infective agent, or to its toxins, both enterotropic and neurotropic. The notable anatomic lesions that certain organs infected by this bacillus present, as, for example, the liver in grave icterus, or, as a result of malignant appendicitis, the kidneys, the myocardium, the spleen, the lungs, the appendix and the intestinal mucosa, show its destructive and local necrosing action. The nature and the colibacillary origin of these have been known for some time. More difficult and less known is the significance of microbic toxins in a number of diseases of the nervous system. It is possible that the Landry syndrome is due to a toxic infection from *Bacillus coli*, at least in certain cases. The blood cultures remain sterile in this disease, but experimentation has shown that rabbits into which the colibacillary neurotoxin is injected develop usually the same symptoms as those observed in the Landry syndrome, and succumb to them. The toxin has often a remote effect in man as well as in animals. This may furnish the pathogenic explanation of certain neuropathic syndromes—psychasthenic or hypochondriac. Serotherapy, the effects of which are so marked in acute infective states (from septicemia to gangrenous appendicitis), may bring about a recovery likewise in a number of other morbid states of obscure pathogenesis, such as those previously mentioned. The fact that antibacillary serotherapy effects a cure in these states gives a demonstration of their nature, which has been hitherto unknown.

*Classification and Etiology of Kidney Diseases in Cases Observed During One Year. L. Velasco Blanco and E. Monferini.—p. 340.

Diabetes Mellitus in Children.—Acuña and Bettinotti report three cases of diabetes in children, aged 1 year and 6 months, 2 years and 4 years, respectively. The first two cases were characterized by a grave condition of the patients. The children presented a picture of marked denutrition and grave acidosis. The youngest of the two patients became comatose, but the coma disappeared after the administration of 75 units of insulin divided into three doses and given during twenty-four hours. The oldest nearly reached the same condition of coma. The administration of a proper diet, according to the age of the patient, and also of insulin given with the two principal meals, gave good results. The first of the children has been observed for three years and the second for one year after the acute attack. In both cases the condition of the children has not permitted the discontinuation of insulin therapy. The third case mentioned by the authors (a child aged 4 years) was one of benign diabetes. A proper diet in this case is enough to keep the child in fairly good condition. Sometimes, however, his condition grows worse as a result of intercurrent infections, and the administration of insulin is necessary. In the three cases marked improvement but not total recovery has been obtained. Two of the patients had had a febrile or infectious disease preceding the appearance of the diabetes. No history of familial diabetes or syphilis of the parents was found in these cases.

Meningococcal Septicemia in Nursling.—Velasco Blanco and Pereda Ramírez report the case of an infant, aged 8 months, who after a rhinopharyngitis manifested a purpuric rash in the gluteal region and legs, at the same time that the temperature rose to 40 C. (104 F.). Four days later the purpuric rash took on the characteristics of purpura with large spots and at the same time a complete picture of meningitis developed; the anterior fontanel was closed. The diagnosis of meningococcal septicemia followed by a secondary meningitis was confirmed by lumbar puncture. Polyvalent antimeningococcal serum in a dose of 10 cc. was given intraspinally and intramuscularly. The patient did well and went on to complete recovery.

Kidney Diseases in Infancy and in Youth.—Velasco Blanco and Monferini state that nephrosis is common in children and in young people. Among 4,115 patients of all ages observed by the authors during one year, thirty-three were children, aged from 4 to 12 years, with nephrosis. Only one of the patients presented a mixed type of renal disease (association of nephrosis with nephritis). In the group of patients with glomerulonephritis there was only one case of chronic nephritis, the remainder being cases of diffuse acute nephritis. Streptococcal infections (and next in importance pneumococcal infections) are the most frequent etiologic factors in the development of diffuse or focal nephritis. Of the thirty-three cases reviewed, the nephropathies were secondary in fifteen cases to scarlet fever, in nine to angina, in two to pyodermitis, in one to parotitis, in two to syphilis and in two to pneumococcal infections; in two cases the etiology was unknown. The tonsils and the lymphoid ring constitute the portal of entry of infections that cause lesions of the kidneys; scarlatinal nephritis is due to the angina scarlatinosa rather than to scarlet fever itself.

*Open Pulmonary Tuberculosis in Children. F. Moses.—p. 161.
*Goiter in Nurslings. K. Rupilius.—p. 173.
Chronic Idiopathic Edema of Genitalia. A. Kollmann.—p. 186.
*Serum Sickness. W. Balaban.—p. 193.

Open Pulmonary Tuberculosis in Children.—On the basis of his observation of 196 cases of open pulmonary tuberculosis in children at a sanatorium from 1921 to 1927, Moses discusses the prognosis of this condition. The after-examinations included the clinical observations, roentgen picture, sputum examination and a determination of the erythrocyte sedimentation speed. Among the 196 children there were 124 girls and 72 boys. In most of the cases the tuberculosis was of the advanced cavernous type. At the end of 1928, it was found that 13 per cent of the children were cured, 24 per cent were ill and 63 per cent were dead. Of fifty-two children who had been under observation for more than six years, 15 per cent were cured, 5 per cent were ill, and 80 per cent were dead. In young children the condition was extremely fatal. The prognosis seemed to be better in boys than in girls. Of the fifty-two children observed for more than six years, fourteen of the twenty boys had died whereas only five of the thirty-two girls were still alive. The prognosis in children in whom the disease was discovered early at health centers while the health of the patient was still good otherwise was better than the general prognosis.

Goiter in Nurslings and Its Treatment.—Rupilius has observed twenty-eight cases of goiter in nurslings. He states that the most important clinical symptoms of this condition are dyspnea, catarrh of the upper respiratory tract, difficulties in taking food, attacks of asphyxia and various forms of stridor. Enlargement of the thyroid is noticed by the parents in less than one half of the cases. A retrosternal goiter can usually be demonstrated by percussion, by roentgen examination and by intensification of the dyspnea and stridor when the head is markedly extended. In the treatment of the goiter, good results were obtained with small doses (0.01, 0.1, 1 mg.) of potassium or sodium iodide. Recurrences were noted in one fifth of the cases, but in all instances the symptoms disappeared again under iodide medication. In some cases a single small dose of iodide so stimulates the metabolism that the goiter disappears.

Serum Sickness.—Balaban states that the repeated administration of serum increases the allergic condition of the organism and that this is manifested by qualitative and quantitative changes in the character of the resulting serum sickness. The intensity of a first attack of serum sickness is determined by the constitutional characteristics of the organism; in a second attack, however, the terrain is of secondary importance and the most important factor is the length of time that the injections have been given. In a second attack of serum sickness several organ systems may become involved in the disease process; namely, the nervous system, blood and blood vessels and glandular apparatus. When the nervous system is affected the most pronounced changes occur in the vasomotor apparatus and the sensory peripheral nerve endings. The blood changes consist in a marked decrease in the number of leukocytes and in manifestations of anemia. Occasionally changes occur in the blood capillaries, and hemorrhagic exanthems and other hemorrhagic manifestations are noted. In other cases there occurs a reactive inflammation of the lymph nodes and hyperplasia of the liver and spleen. In some cases the effect of the anaphylactic shock on the underlying pathologic condition is negative but in some it is favorable.

Actions of Hormone of Anterior Lobe of Hypophysis.—Falta and Högler investigated the actions of the hormone of the anterior lobe of the hypophysis. First they tested the influence of a hypophyseal preparation on the production of body heat. In the majority of cases they found a considerable reduction, not only in the cases with a normal basal metabolism but also in those with increased or decreased basal metabolism. Further, the effect on the carbohydrate metabolism was investigated. It appears that the hormonal preparation influences the carbohydrate metabolism only when insulin is present. It is not certain, however, whether this applies to all cases. In persons without diabetic symptoms, who were given insulin in combination with a cure of forced feeding, there was no marked modification of the carbohydrate metabolism in the sense of hypoglycemic manifestations. On the contrary, in some instances it appeared as if an increased sensitivity to insulin developed. The authors further investigated the action of the hormonal preparation of the anterior lobe of the hypophysis on the process of growth and on the genitalia. In two cases of infantilism it was found that growth could be stimulated with the hormonal preparation; however, in two cases of eunuchoidism the growth was not stimulated. With regard to the problem of whether all the actions of the extract of the hormone of the anterior lobe of the hypophysis are produced by one elementary substance or whether the extract contains several hormones, the authors state that most investigators are now inclined to believe that the anterior lobe produces several hormones. They themselves did not investigate this problem but they found that the substance extracted from the urine of pregnant women influences the metabolism, the growth and also the genital sphere.

Bartonella Anemia and Feeding with Liver.—Careful observations on rats with bartonella anemia that were fed with liver convinced Neumann that liver influences bartonella anemia in splenectomized rats not favorably but unfavorably. He also thinks that there is not an analogy between bartonella anemia and pernicious anemia, and that bartonella anemia is not a suitable test object for the efficacy of liver therapy.

Experimental Investigations on Liver Diet.—Friedemann and Deicher refer to former experiments in which they fed liver to rats with bartonella anemia. In a first group of animals they observed a favorable influence of liver on bartonella anemia; in a second group, however, the favorable influence was absent. Neumann, who in the preceding article reports entirely negative results, expresses the opinion that the animals that Friedemann and Deicher used for their first experiments had a special resistance power against bartonella anemia or were latently infected with bartonella of low virulence. Friedemann and Deicher do not accept this explanation of Neumann's but think that perhaps the genus of animals from which the liver is taken is the cause of the contradictory results. It is known that hog liver has little effect on pernicious anemia. In this respect Neumann's experiments differ from those conducted by Friedemann and Deicher, for while the latter used beef liver, Neumann used mostly liver from guinea-pigs.

Modifiability of Cheyne-Stokes Respiration by Means of Histamine.—On the basis of observations on nine patients with Cheyne-Stokes respiration, who were given intravenous injections of histamine, Kisch comes to the conclusion that by means of histamine injections Cheyne-Stokes respiration can be suppressed. The effects of an injection may last several hours. If the histamine treatments are repeated and are followed by a suitable cardiovascular therapy, the improvement may be permanent. It is probable that the histamine acts by increasing the amount of the circulating blood and thus causes also a better blood perfusion of the brain and of the centers of respiration.

Functional Tests of Kidney in Surgical Diseases.—Wildegans points out that, for the diagnosis of surgical diseases of the kidney, functional tests are of great significance. However, because of the numerous methods described in the literature it is difficult for the practitioner to decide which methods are the most practical and reliable. Therefore the author describes and evaluates the various methods. First he discusses several blood tests such as determination of the rest nitrogen, the indican test, the creatinine test, cryoscopy and Ambard's formula. In the latter test the urea content of both the blood and the urine is determined. Other methods discussed are the water and concentration tests, the determination of the urea elimination of each kidney, the urea tolerance test, comparative cryoscopy of the urine eliminated by each kidney, the phlorhizin test, experimental polyuria according to Albarran, the indigo carmine test, the phenolsulphonphthalein test, the determination of the hydrogen ion concentration, various methods of pyelography, especially that form in which the contrast medium is injected intravenously, and finally pyeloscopy. The different tests give a picture of the various partial functions of the kidney. However, it is not always permissible to estimate the intactness of the renal parenchyma on the basis of the functional activity. A high degree of functional insufficiency does not always go parallel with extensive anatomic defects, and on the other hand great anatomic defects may exist when the function is only slightly abnormal. Absolutely reliable indications should not be expected from any of the tests. However, in combination with other diagnostic methods they are of value. It is also pointed out that functional tests are valuable after the operative treatment. They enable the surgeon to determine whether, after one kidney is removed, the remaining one is capable of eliminating all metabolic waste material.

Malaria-Like, Painless Form of Cholelithiasis.—Ehrmann directs attention to a comparatively unknown form of cholelithiasis. The disease becomes manifest in a painless, malaria-like fever. On the basis of careful bacteriologic tests it may be assumed that the disturbance is caused by a temporary colibacillemia. In the treatment, methenamine and quinine have proved helpful.

Unusual Deposition of Calcium in Connective Tissue.—Cohn and Freye report the case of a youth, aged 17, with extensive calcium deposits. Two photographs of the patient show calcium tumors on the shoulders, arms and back and also deformed hands. Four roentgenograms reveal calcium deposits in the tissues. The anamnesis disclosed that the first induration had been observed at the age of 4. This was incised, but similar ones developed soon after. Occasionally spontaneous perforation occurred and friable grayish white masses were discharged. When the patient came under the authors' observation, movement in the upper extremities was greatly reduced, so that the patient was practically helpless. Because other authors had obtained favorable results with roentgen therapy in cases of bursitis with calcareous degeneration, the authors instituted roentgen irradiation in this case. At each treatment 0.2 unit skin dose was applied. The irradiations were repeated at intervals of two days and it was found that, after several treatments had been applied to the left shoulder, the patient could lift the arm almost to the horizontal level. It is assumed that the roentgen rays effect an acidification in the tissues, by which the calcium compounds are decomposed. It appears contradictory when it is considered that roentgen rays are also employed to stimulate better callus formation following fracture of bones. When discussing the pathogenesis of calcinosis the authors express the opinion that it is due to a constitutional anomaly in the calcium metabolism.

Etiology and Symptomatology of Thrombosis of Mesenteric Veins.—Jacobi reports two cases of thrombosis of the mesenteric veins with hemorrhagic infarction of the intestine, both of which had a fatal outcome. The first case is of especial interest on account of its etiology. The thrombosis of the mesenteric and portal veins followed an enteritis. This pathogenesis, which could be expected in most instances, is in realty extremely rare. In most cases of thrombosis of the mesenteric veins the etiology cannot be determined. Mesenteric thrombosis usually presents the clinical aspects of ileus or of perforation peritonitis. The infarcted segment of the intestine loses its tonus and its motility and thus causes an atonic intestinal occlusion and severe meteorism. Bloody stools, one of the most characteristic symptoms of intestinal infarction, was not manifest in either of the two cases. The author further discusses the differential diagnosis and the treatment. He states that the prognosis is usually unfavorable.

Disturbance of Liver in Cinchophen Intoxication.—Cinchophen, which is employed in the treatment of gout and arthritis, may cause more or less severe complications. Vajda describes two cases of cinchophen intoxication which resulted from incorrect dosage. The patients developed gastro-intestinal disorders and icterus and the disease had the aspects of acute hepatitis. With consideration of similar reports in the literature, the significance of the correct application and dosage is stressed

Treatment of Constipation.—After discussing some causes of sluggishness of the intestine and after differentiating between atonic and spastic constipation, von Noorden discusses the treatment of chronic sluggishness of the intestine by means of a diet containing large amounts of roughage. Then he discusses psychotherapy and massage. In the evaluation of abdominal massage it is pointed out that deep massage is unsuitable, especially in spastic constipation. However, the more superficial and rotating massage has a soothing and spasmolytic effect. Further, the various medicaments are evaluated, first the different oily substances and then the salines. It is stated that yeast has been used in cases of occasional constipation for several decades. The author recalls that bakers' yeast was used for this purpose during his childhood, about sixty years ago. However, the medical literature mentions it only several decades later. Besides the purgative effect, yeast also has nutritional value because of its richness in vitamins. However, yeast that still has fermentative power is not always advisable in cases of functional sluggishness of the intestine because, if it is given in effective quantities, it often causes irritative conditions in the stomach and the intestine. In the last part of the article the constipation of obese persons is discussed and Banting's treatment is recommended. Besides other favorable effects this diet also decreases the cholesterol content of the blood, which is found considerably increased not only in obese persons with constipation but also in other patients with constipation. The author's observations have convinced him that the counteraction of hypercholesteremia effects the cure of many disorders in the sympathetic nervous system, among them also spastic constipation and exudative diathesis. It is also assumed that the favorable effects of certain raw fruit and vegetable diets on inflammatory and trophic tissue disturbances is due to the fact that they counteract hypercholesteremia.

Treatment of Tuberculosis of Skin with Consideration of Dietary Therapy.—Blumenthal first discusses the therapeutic methods that formerly were employed in tuberculosis of the skin. The object of most of them was to remove the local focus of tuberculosis. The advantage of these treatments was that they were rapid. However, they caused unsightly scars and relapses were frequent. In recent years it has been more and more recognized that tuberculosis of the skin is usually only a part of a more generalized infection and that a treatment is necessary that will influence the entire organism. Light therapy, which was introduced by Finsen, was first given as a local treatment. Later, however, it was used as a generalized treatment. Besides tuberculin, preparations of arsenic, copper and gold were employed in tuberculosis of the skin. The most recent addition to the general treatments of tuberculosis of the skin is the dietary treatment that was introduced by Gerson and later investigated and adopted by Sauerbruch and Herrmannsdorfer. The author, in employing this diet, observed that ulcerations healed and lupus nodules disappeared under its influence. In children however, the dietary treatment was not so successful. In one boy the tuberculosis of the skin became even more severe during the diet. It may be assumed that perhaps the diet does not supply all the substances necessary in the growth of children. It was also noted that patients who underwent the dietary treatment showed a susceptibility for infections such as furuncle, folliculitis and staphylococcic foci. The hemograms of the patients were studied at regular intervals and also the sedimentation speed. The results of these tests indicated a steady progress in the healing process. In the last part of the article the author advises that the exclusive dietary treatment should be abandoned. He recommends the dietary treatment and the general light therapy as a foundation in all cases of tuberculosis of the skin. Local treatments should be combined with these general methods, and the local methods may be modified to suit the individual case.

Fate of Patients with Goiter Following Treatment with Ergotamine Tartrate.—Adlersberg and Porges report the results of the after-examination of patients, who, during 1924 and 1925, had been treated with ergotamine tartrate. During the stay at the hospital the ergotamine tartrate had been administered subcutaneously. After the patient left the hospital, peroral administration was resorted to The treatments were given in periods of from two to three weeks The intervals between were from one to three weeks. At the beginning of by intensification of the dyspnea and stridor when the head is markedly extended. In the treatment of the goiter, good results were obtained with small doses (0.01, 0.1, 1 mg.) of potassium or sodium iodide. Recurrences were noted in one fifth of the cases, but in all instances the symptoms disappeared again under iodide medication. In some cases a single small dose of iodide so stimulates the metabolism that the goiter disappears.

Serum Sickness.—Balaban states that the repeated administration of serum increases the allergic condition of the organism and that this is manifested by qualitative and quantitative changes in the character of the resulting serum sickness. The intensity of a first attack of serum sickness is determined by the constitutional characteristics of the organism; in a second attack, however, the terrain is of secondary importance and the most important factor is the length of time that the injections have been given. In a second attack of serum sickness several organ systems may become involved in the disease process; namely, the nervous system, blood and blood vessels and glandular apparatus. When the nervous system is affected the most pronounced changes occur in the vasomotor apparatus and the sensory peripheral nerve endings. The blood changes consist in a marked decrease in the number of leukocytes and in manifestations of anemia. Occasionally changes occur in the blood capillaries, and hemorrhagic exanthems and other hemorrhagic manifestations are noted. In other cases there occurs a reactive inflammation of the lymph nodes and hyperplasia of the liver and spleen. In some cases the effect of the anaphylactic shock on the underlying pathologic condition is negative but in some it is favorable.

Functional Tests of Kidney in Surgical Diseases.—Wildegans points out that, for the diagnosis of surgical diseases of the kidney, functional tests are of great significance. However, because of the numerous methods described in the literature it is difficult for the practitioner to decide which methods are the most practical and reliable. Therefore the author describes and evaluates the various methods. First he discusses several blood tests such as determination of the rest nitrogen, the indican test, the creatinine test, cryoscopy and Ambard's formula. In the latter test the urea content of both the blood and the urine is determined. Other methods discussed are the water and concentration tests, the determination of the urea elimination of each kidney, the urea tolerance test, comparative cryoscopy of the urine eliminated by each kidney, the phlorhizin test, experimental polyuria according to Albarran, the indigo carmine test, the phenolsulphonphthalein test, the determination of the hydrogen ion concentration, various methods of pyelography, especially that form in which the contrast medium is injected intravenously, and finally pyeloscopy. The different tests give a picture of the various partial functions of the kidney. However, it is not always permissible to estimate the intactness of the renal parenchyma on the basis of the functional activity. A high degree of functional insufficiency does not always go parallel with extensive anatomic defects, and on the other hand great anatomic defects may exist when the function is only slightly abnormal. *Absolutely reliable indications should not* be expected from any of the tests. However, in combination with other diagnostic methods they are of value. It is also pointed out that functional tests are valuable after the operative treatment. They enable the surgeon to determine whether, after one kidney is removed, the remaining one is capable of eliminating all metabolic waste material.

Malaria-Like, Painless Form of Cholelithiasis.—Ehrmann directs attention to a comparatively unknown form of cholelithiasis. The disease becomes manifest in a painless, malaria-like fever. On the basis of careful bacteriologic tests it may be assumed that the disturbance is caused by a temporary colibacillemia. In the treatment, methenamine and quinine have proved helpful.

Unusual Deposition of Calcium in Connective Tissue.—Cohn and Freye report the case of a youth, aged 17, with extensive calcium deposits. Two photographs of the patient show calcium tumors on the shoulders, arms and back and also deformed hands. Four roentgenograms reveal calcium deposits in the tissues. The anamnesis disclosed that the first induration had been observed at the age of 4. This was incised, but similar ones developed soon after. Occasionally spontaneous perforation occurred and friable grayish white masses were discharged. When the patient came under the authors' observation, movement in the upper extremities was greatly reduced, so that the patient was practically helpless. Because other authors had obtained favorable results with roentgen therapy in cases of bursitis with calcareous degeneration, the authors instituted roentgen irradiation in this case. At each treatment 0.2 unit skin dose was applied. The irradiations were repeated at intervals of two days and it was found that, after several treatments had been applied to the left shoulder, the patient could lift the arm almost to the horizontal level. It is assumed that the roentgen rays effect an acidification in the tissues, by which the calcium compounds are decomposed. It appears contradictory when it is considered that roentgen rays are also employed to stimulate better callus formation following fracture of bones. When discussing the pathogenesis of calcinosis the authors express the opinion that it is due to a constitutional anomaly in the calcium metabolism.

Etiology and Symptomatology of Thrombosis of Mesenteric Veins.—Jacobi reports two cases of thrombosis of the mesenteric veins with hemorrhagic infarction of the intestine, both of which had a fatal outcome. The first case is of especial interest on account of its etiology. The thrombosis of the mesenteric and portal veins followed an enteritis. This pathogenesis, which could be expected in most instances, is in realty extremely rare. In most cases of thrombosis of the mesenteric veins the etiology cannot be determined. Mesenteric thrombosis usually presents the clinical aspects of ileus or of perforation peritonitis. The infarcted segment of the intestine loses its tonus and its motility and thus causes an atonic intestinal occlusion and severe meteorism. Bloody stools, one of the most characteristic symptoms of intestinal infarction, was not manifest in either of the two cases. The author further discusses the differential diagnosis and the treatment. He states that the prognosis is usually unfavorable.

Disturbance of Liver in Cinchophen Intoxication.—Cinchophen, which is employed in the treatment of gout and arthritis, may cause more or less severe complications. Vajda describes two cases of cinchophen intoxication which resulted from incorrect dosage. The patients developed gastro-intestinal disorders and icterus and the disease had the aspects of acute hepatitis. With consideration of similar reports in the literature, the significance of the correct application and dosage is stressed.

Treatment of Constipation.—After discussing some causes of sluggishness of the intestine and after differentiating between atonic and spastic constipation, von Noorden discusses the treatment of chronic sluggishness of the intestine by means of a diet containing large amounts of roughage. Then he discusses psychotherapy and massage. In the evaluation of abdominal massage it is pointed out that deep massage is unsuitable, especially in spastic constipation. However, the more superficial and rotating massage has a soothing and spasmolytic effect. Further, the various medicaments are evaluated, first the different oily substances and then the salines. It is stated that yeast has been used in cases of occasional constipation for several decades. The author recalls that bakers' yeast was used for this purpose during his childhood, about sixty years ago. However, the medical literature mentions it only several decades later. Besides the purgative effect, yeast also has nutritional value because of its richness in vitamins. However, yeast that still has fermentative power is not always advisable in cases of functional sluggishness of the intestine because, if it is given in effective quantities, it often causes irritative conditions in the stomach and the intestine. In the last part of the article the constipation of obese persons is discussed and Banting's treatment is recommended. Besides other favorable effects this diet also decreases the cholesterol content of the blood, which is found considerably increased not only in obese persons with constipation but also in other patients with constipation. The author's observations have convinced him that the counteraction of hypercholesteremia effects the cure of many disorders in the sympathetic nervous system, among them also spastic constipation and exudative diathesis. It is also assumed that the favorable effects of certain raw fruit and vegetable diets on inflammatory and trophic tissue disturbances is due to the fact that they counteract hypercholesteremia.

Treatment of Tuberculosis of Skin with Consideration of Dietary Therapy.—Blumenthal first discusses the therapeutic methods that formerly were employed in tuberculosis of the skin. The object of most of them was to remove the local focus of tuberculosis. The advantage of these treatments was that they were rapid. However, they caused unsightly scars and relapses were frequent. In recent years it has been more and more recognized that tuberculosis of the skin is usually only a part of a more generalized infection and that a treatment is necessary that will influence the entire organism. Light therapy, which was introduced by Finsen, was first given as a local treatment. Later, however, it was used as a generalized treatment. Besides tuberculin, preparations of arsenic, copper and gold were employed in tuberculosis of the skin. The most recent addition to the general treatments of tuberculosis of the skin is the dietary treatment that was introduced by Gerson and later investigated and adopted by Sauerbruch and Herrmannsdorfer. The author, in employing this diet, observed that ulcerations healed and lupus nodules disappeared under its influence. In children however, the dietary treatment was not so successful. In one boy the tuberculosis of the skin became even more severe during the diet. It may be assumed that perhaps the diet does not supply all the substances necessary in the growth of children. It was also noted that patients who underwent the dietary treatment showed a susceptibility for infections such as furuncle, folliculitis and staphylococcic foci. The hemograms of the patients were studied at regular intervals and also the sedimentation speed. The results of these tests indicated a steady progress in the healing process. In the last part of the article the author advises that the exclusive dietary treatment should be abandoned. He recommends the dietary treatment and the general light therapy as a foundation in all cases of tuberculosis of the skin. Local treatments should be combined with these general methods, and the local methods may be modified to suit the individual case.

Fate of Patients with Goiter Following Treatment with Ergotamine Tartrate.—Adlersberg and Porges report the results of the after-examination of patients, who, during 1924 and 1925, had been treated with ergotamine tartrate. During the stay at the hospital the *ergotamine tartrate* had been administered subcutaneously. After the patient left the hospital, peroral administration was resorted to. The treatments were given in periods of from two to three weeks. The intervals between were from one to three weeks. At the beginning of each period of treatment one tablet of 1 mg. was given three times daily. Later two tablets were given each time, then three tablets and in some instances even four tablets. Then the dosage was gradually reduced again. During this method of application, toxic effects did not become manifest. The ergotamine tartrate effects a calming and retardation of the heart action and improvement in the general condition. Insomnia gradually ceases and the patient regains weight and strength. While oral administration is harmless, subcutaneous injections of ergotamine tartrate have to be given with great care. Some of the patients continued the treatment for only a short time after they left the hospital, whereas others continued it intermittently until a more recent date. Of twenty-two patients who had received the treatment, thirteen appeared for after-examination. Nearly all of these were cured. Treatment with ergotamine tartrate proved helpful likewise in tachycardia of nervous origin.

Stomach Powder in Treatment of Pernicious Anemia.—Decastello discusses the significance of recent investigations of American authors on the importance of the stomach in the pathogenesis and in the treatment of pernicious anemia. A stomach powder was employed by the author in eight cases of pernicious anemia, and in all of them the results were favorable.

Pernicious Anemia Refractory to Liver Treatment, Favorably Influenced by Desiccated Stomach.—Leschke states that, in cases of pernicious anemia that are refractory to liver treatment, the blood formation can be stimulated by desiccated stomach. It is probable that the liver and the stomach contain two antianemic factors, which are both present in raw (not in desiccated) liver and also in the raw and in the dried stomach. One of these factors is effective in pernicious anemia and the other in secondary anemia. Stomach powder should be given in sufficiently large doses. The patient should receive three times daily about 10 Gm. of the powder together with meat that has been fried only slightly, and with large doses of hydrochloric acid and pepsin.

Aspects of Hypophyseal Cachexia.—Reiche describes the clinical aspects and the results of the necropsy in a case of hypophyseal cachexia. The case is notable for certain unusual aspects. 1. The age of the patient, 65 years, was comparatively high. 2. The course of the disease was protracted, the beginning dating back to the age of 21. 3. The patient did not show the extreme emaciation noted in most cases of hypophyseal cachexia. The disease was characterized by a strong reduction of the bodily energy, mental dulness, falling out of teeth and of hair, and by a dry waxy skin. 4. Eosinophilia was absent. 5. The body temperature and the blood pressure were not reduced, as is usually the case. 6. The sugar metabolism was likewise normal. 7. The patient had attacks of coma. 8. Simultaneously with the signs of hypophyseal cachexia there existed certain symptoms of myxedema.

Treatment of Various Forms of Anemia.—Herz stresses that anemia may be caused by various factors. He mentions chlorosis, pernicious anemia, hemolytic icterus, aplastic anemia and hemorrhagic anemia. It is essential that the treatment in the various forms should be decided on the basis of the pathogenesis. The therapeutic methods that are evaluated by the author are: injection of hemostatics, blood transfusion, intramuscular injection of physiologic solution of sodium chloride, medication with iron or with arsenic preparations, liver treatment, desiccated stomach and, finally, extirpation of the spleen.

Spasm of Coronary Vessels.—Goldenberg and Rothberger point out that the opinion is still widely held that an ambulatory attack of angina pectoris is caused by a spasm of the coronary arteries. This theory is understandable when it is considered that it dates back to a time when the diagnosis of a cardiac infarct was not possible intra vitam, and when the symptoms of an acute occlusion of a branch of the coronary arteries was included in the term angina pectoris. The authors consider the cardiac infarct as an independent disease entity, which, in order to differentiate it from an ambulatory attack of angina pectoris, should be designated by a special term; namely, cardiac infarct. It is shown that the theory in which angina pectoris is considered as a result of a coronary spasm is no longer tenable. The following problems were investigated in animal experiments: 1. What are the attendant phenomena of a coronary spasm? 2. Do similar phenomena occur during an ambulatory attack of angina pectoris? In order to answer these questions experiments were made on dogs. Coronary spasms were produced by injections of a preparation of the pressor principle of the posterior lobe of the hypophysis and then the changes in the electrocardiogram were studied. The electrocardiogram following ligation of the left coronary artery showed similar changes. When these electrocardiograms of the animals were compared with those made in human beings during occlusion of a coronary branch, a great similarity was noted. However, the electrocardiogram during an attack of angina pectoris does not show the same changes and it may therefore be assumed that angina pectoris is not caused by a spasm of the coronary arteries.

New Problems in Pathologic Anatomy of Tuberculosis.—Sternberg states that the results of numerous postmortem examinations and of tuberculin tests have proved that the majority of human beings, especially in large cities, pass through a tuberculous infection usually during childhood. The infection is caused by the respired air and the portal of entry is the lung. A placental or intra-uterine infection may occur in some cases; however, it is comparatively rare. The anatomic proof of this early tuberculous infection is the so-called primary complex which involves two factors, the primary focus and the infection of the regional lymph nodes. In the lung the primary focus can usually be detected, but in the other organs, especially in the intestine, the detection is more difficult. Sometimes the primary complex is followed by a dissemination of the tuberculosis or by a generalized infection. In the majority of cases, however, the primary complex heals. If in later life a new infection takes place, this is usually not a reinfection but rather a superinfection, because the primary complex had not yet completely healed. While the primary infection usually causes exudative processes, the secondary infection leads to proliferative processes. The first tuberculous infection is generally in the middle portion of the lung. Formerly it was usually assumed that the apex of the lung was the location of the second infection. Clinicians and roentgenologists now hold that the first postprimary focus is not in the apex but usually develops from an exudative focus in the infraclavicular region, and that the dissemination is not gradual but rather sporadic.

*Acne in Pulmonary Tuberculosis. R. Griesbach.—p. 405.

Acid-Base Balance and Ionized Calcium Content of Blood in Tuberculosis.—*By means of the electrometric* method utilizing a quinhydrone electrode, Varela et al. demonstrated that throughout the course of pulmonary tuberculosis the hydrogen ion concentration of the plasma remains within the normal limits, even in the severe evolutionary forms. The total carbon dioxide of the unchanged plasma varied between 51.3 and 65.3 per cent by volume, fluctuating within narrow limits about an average normal value of 57.4. In none of the patients examined was there a tendency to alkalosis. Both the total calcium of the serum and the fraction of ionized calcium remained within the normal limits. During a Sauerbruch-

Herrmannsdorfer-Gerson mineral diet treatment the acid-base balance in the blood did not fluctuate and the total calcium and the ionized calcium remained within the normal limits.

Method for Determination of Phagocytosis of Tubercle Bacilli with Phagocytes of Tuberculous Persons.—Westenrijk determines in vitro the phagocytosis of tubercle bacilli by phagocytes of tuberculous persons. By means of a Pasteur pipet ten drops of blood are removed from the patient's finger, mixed with an equal quantity of a 1.5 per cent solution of sodium citrate, and centrifugated; the excess of citrate serum is then removed and the remainder washed twice in a centrifuge with an equal quantity of sodium chloride solution. Three drops of the remaining thin layer of leukocytes are transferred to a small tube by means of a pipet and to it is added an equal amount of standardized emulsion of bacilli. The mixture is allowed to stand an hour in an incubator at 38 C. and then is carefully shaken and some of it is transferred to a slide. The preparation is fixed by adding an excess of methyl alcohol and allowing it to stand in an incubator until dry. It is then stained with Ziehl's carbolfuchsin solution, decolorized with a 2.5 per cent solution of sulphuric acid and dilute alcohol and stained again with a saturated solution of methylthionine chloride. The degree of phagocytosis is determined by counting the number of phagocytes that have ingested tubercle bacilli, regardless of whether they contain only one or several bacilli. At least 200 phagocytes, chiefly the polymorphonuclears, should be counted; in children in whom only a few polymorphonuclears are present, one should include in the count the large mononuclears that contain an immature nucleus.

Acne in Pulmonary Tuberculosis: Etiology.—Griesbach does not accept the theory that the frequent occurrence of acne in persons with pulmonary tuberculosis can be explained on the basis of the increased perspiration and the seborrheic terrain. He believes that as a result of a suddenly increased dissemination of tubercle bacilli, their toxins and metabolic products, the defense power of the reticulo-endothelial system is mobilized at once and responds. Since the reticulo-endothelial apparatus, however, is the place of formation not only of purely specific antibodies but of nonspecific ones, it may be so weakened by its response to the toxin of the tubercle bacillus that it no longer furnishes sufficient antibodies against other infectious noxae. Staphylococci in the skin, which otherwise would not cause a disturbance, now multiply rapidly and produce acne.

*Hoehne's Sign as Only Indication in Atypical Rupture of Uterus. V. Lazarević.—p. 2466.

Investigations on Predisposition to Edema During Pregnancy.—Baráth and von Magyary point out that hydropic conditions occur frequently during pregnancy. The dropsy of gravidity with its symptoms of edema, albuminuria, cylindruria and hypertension is generally considered to be the result of renal disorders. However, examination of pregnant women with slight edema revealed that the renal function was normal, and gynecologists have expressed the opinion that the predisposition to edema during gravidity is probably due to extrarenal factors. Experiments were made on pregnant women with and without edema. By means of an intradermal injection of 0.2 cc. of an 0.8 per cent solution of sodium chloride it was determined whether the resorption of the wheal, which in normal persons requires from fifty to sixty minutes, is more rapid in pregnant women. The various protein constituents of the blood were likewise determined. The fibrinogen content was considerably increased, and the albumin-globulin quotient was decreased. Parallel with this there was a decrease in the swelling capacity of the blood colloids and an increase in the water resorption capacity of the tissue colloids. The authors give tabular reports of their tests and conclude that during the last months of pregnancy there is an accelerated resorption of intradermally injected solutions of sodium chloride, and frequently also a shifting of the blood proteins in the direction of the coarsely dispersed protein constituents, and a decrease in the colloid osmotic pressure of the blood serum. Since renal disturbances do not exist it may be assumed that the slight edema in pregnant women is due to an increased water resorption capacity of the tissue colloids during the last months of pregnancy.

Complications Following Ligation of Vena Cava During Puerperal Pyemia.—Fels and Bettinger state that the opinions regarding the therapeutic value of ligation of the vena cava in puerperal pyemia are still divided. The authorities disagree likewise as to which is the most opportune time for the ligation, whether it should be done early or whether an expectant attitude is advisable in the beginning. The authors do not oppose ligation of the vena cava but consider it of value in some cases of puerperal pyemia. The case of a primipara, aged 29, is reported because it shows the danger of a complication that so far has not received sufficient attention. The ligation performed in this case at first appeared to be successful. Then, twenty-three days after the operation, the patient suddenly developed high fever and died shortly after. The necropsy revealed that the silk thread used for the ligation had cut the vessel and a hematoma had formed. Because even the thickest silk thread does not eliminate the danger of cutting the vessel, it is perhaps advisable to use different material for the ligation. The use of catgut is not advisable because it is too quickly resorbed. A linen ribbon such as is used for ligation of the umbilical cord might be helpful; however, the foreign body irritation might be too great. The use of a strip from the fascia lata of the thigh appears to be most advantageous, because it is not resorbed too quickly and may be made as wide as seems necessary.

Hoehne's Sign as Only Indication in Atypical Rupture of Uterus.—Lazarević gives the clinical history of a woman, aged 25. The labor was difficult because of an abnormal position of the fetus. When injections of hypophyseal preparations did not stimulate the contractions sufficiently, the patient was brought to the hospital. Here hypophyseal preparations were again administered, but now they had no effect at all. The complete absence of uterine contractions during birth, in spite of repeated administrations of hypophyseal preparations (Hoehne's sign), was taken as an indication of a rupture of the uterus although there was no shock effect and there were no other signs indicating rupture. The delivery was completed by laparotomy. It was found that the uterus had ruptured. The tear was 12 cm. long. The entire placenta and nearly one half of the comparatively large male fetus were in the peritoneal cavity. The fact that the woman had felt a severe pain while being brought to the hospital makes it appear probable that the rupture occurred then. The author reports this case in order to direct attention to the diagnostic value of Hoehne's sign.

Culture of Plasmodium Malariae.—Aga-Han's experiments with the cultivation of *Plasmodium malariae* on various culture mediums showed that the organism grows well in vitro only in the presence of partially hemolyzed erythrocytes. He used distilled water as a hemolyzing agent and recommends a culture medium consisting of human serum 2 cc., neutral distilled water 8 cc. and erythrocytes 2 cc. The optimal temperature for the culture was 37 C., and the blood specimens were taken from the patients during the period of the chill or just at the beginning of the rise of the temperature, when both macrogametes and microgametes may be secured. He never failed to get a good growth on this culture medium.

Experimental Study of Theories of Sedimentation Test.—Levine studied experimentally the rôle of the erythrocytes and of the blood plasma as determining factors in the production of the sedimentation test. In the first series of the experiments, a 0.9 per cent solution of sodium chloride was gradually added to the specimens of blood from patients with various diseases. The sedimentation test was accelerated in the beginning, in the weak (1 to 10) dilutions of the blood with the sodium chloride, but gradually slowed considerably with the increase in the dilution of the blood. In the second series, the erythrocytes from the patients with various diseases were thoroughly washed from all traces of the blood plasma and placed in suspension in the 0.9 per cent solution of sodium chloride, in the same proportion as they were in their respective blood. The sedimentation test was slowed to the highest degree and became practically the same in all suspensions of the erythrocytes from the patients with various diseases. However, when the erythrocytes were removed from the sodium chloride solution and replaced in their respective blood plasma, the sedimentation test assumed the individual characteristics of the various diseases. For instance, in a healthy person, in the blood it was 3.5; in the suspension of the erythrocytes in the sodium chloride solution it was 1.25 and after the addition of the erythrocytes to the plasma it rose to 3.2. In the same order in scurvy it was: 51 : 1.25 : 44; in gonorrhea, 7.5 : 1.2 : 7.2; in syphilis, 47 : 1.3 : 44; in eczema, 24 : 1.2 : 20.1, and so on. From this the author draws the conclusions, first, that Stokes's *mechanical theory of the sedimentation test was disproved by* the fact that the sedimentation was slowed after the dilution of the blood with the solution of sodium chloride, and not accelerated as it should have been according to this theory; and, secondly, that the determining factor in the sedimentation test is the blood plasma, because the sedimentation test in the suspension of the erythrocytes washed from their respective plasma, in the solution of sodium chloride, was the same in the patients with various diseases. The fact that, after the erythrocytes were removed from the sodium chloride solution and replaced in their respective blood plasma, the sedimentation test showed again the differences characteristic for each disease, proves that the pathologic changes in the blood plasma cause secondarily some reversible physicochemical changes in the erythrocytes conserving the electrical charges carried by the erythrocytes and the phenomena of adsorption, as it was suggested by the third series of experiments, in which the volume of the precipitated erythrocytes was measured under the same conditions as in the first two series.

Acta Radiologica, Stockholm

11: 347-453 (Sept. 30) 1930

Curietherapy: Dosage: New Method of Measuring. J. Murdoch.—p. 350.
*Case of Generalized Osteitis Deformans (Paget) with Secondary Malignant Degeneration. V. Genner and H. Boas.—p. 398.
Roentgen Examination of Recruits for Swiss Army. H. E. Walther.—p. 411.
Experimental Study of Effects of Thallium on Rats and Mice. R. Baumann.—p. 425.
*On Great Gastric Retention and Dilatation of Stomach in Cases of Gastroduodenal Ulcer and Cancer of Stomach. T. Klason.—p. 444.

Generalized Osteitis Deformans (Paget) with Secondary Malignant Degeneration.—Genner and Boas report a typical case, in a man, aged 51, of about thirty years' standing. Its course had not been attended with any disturbance of his general health or fitness for work. It was not discovered until he was admitted to the hospital to be treated for an intumescence of his right shoulder, the result of an injury to that region, sustained a few weeks previously. The roentgen examination then disclosed the fact that the swelling was due to a malignant neoformation in the osseous tissue there, and that he was suffering from a generalized form of osteitis deformans (Paget), with typical deformation of some of the bones, especially those of the lower extremities (saber legs). He died a few weeks later, as a result of the secondary, new malignant development, and the necropsy confirmed the clinical and roentgen diagnosis, revealing extensive sarcomatous destruction of the right scapula, clavicle and part of the head of the humerus, with large hemorrhagic tumor masses. Besides, the patient had syphilis, acquired when he was 18 years old. It had been poorly treated, and the Wassermann reaction was still strongly positive. Another feature of the case was the pronounced deafness of the patient during the last few months of his life, evidently a result of the osteosclerotic processes characteristic of the disease.

Dilatation of Stomach in Cases of Gastroduodenal Ulcer and Cancer of Stomach.—Klason investigated the frequency with which much retention and dilatation of the stomach occur in cases of gastroduodenal ulcer and cancer of the stomach. In 451 cases of ulcer, this complication was present 39 times. Of the ulcers, 258 were of the duodenal variety and in these cases great gastric retention occurred 28 times. The gastric ulcers numbered 193 and the complication occurred in 11 cases. In 201 cases of cancer of the stomach great retention and dilatation of the stomach were found only in cases of cancer of the canalis, being present in 30 cases out of 97, and in 14.3 per cent of all cases of cancer of the stomach.

Ugeskrift for Læger, Copenhagen

92: 865-886 (Sept. 1) 1930

*Positive Pirquet Reaction in First Three Years of Life. R. Kjer-Petersen and J. Ostenfeld.—p. 865.
*Undulant Fever: Case. C. Ebskov and H. Harpøth.—p. 872.
*Insulin in Treatment of Undernutrition. H. H. Jacobsen.—p. 875.

Positive Pirquet Reaction in First Three Years of Life.—Kjer-Petersen and Ostenfeld's material from tuberculosis clinics comprise 293 cases with a positive reaction. In 209 cases there was open tuberculosis in the home and in only forty cases was the home free from sources of infection. Examination at least five years later showed that of the fifty-three patients with a positive Pirquet reaction in the first year twenty had died (nine before the end of the third year); nineteen of tuberculosis, and thirty-two were well; of the ninety-one in the second year fourteen had died, thirteen of tuberculosis, and seventy-four were well; of the 149 in the third year fifteen had died, thirteen of tuberculosis, and 133 were well. They conclude that in the case of a child in the second or third year with a positive Pirquet reaction and no other symptoms, expectant treatment is justified when the home conditions are hygienic and examinations are made at suitable intervals; in the case of a child in the first year with a positive reaction, particular attention is required to determine whether special treatment is necessary or continued control sufficient.

Undulant Fever: Case.—In the case reported by Ebskov and Harpøth, undulant fever concurred with an anemia of the pernicious type, hemolytic jaundice and chronic nephritis with aortic insufficiency. The diagnosis was confirmed on necropsy. The nephritis is thought to have been primary and, together with the cardiac disorder, of far earlier origin than the undulant fever. The hemolytic jaundice is assumed to have been due to the infection.

Insulin in Treatment of Undernutrition.—Jacobsen treated twenty-one patients with small doses of insulin and extra meals, by which insulin shock was prevented. No deleterious effects were noted. In his opinion the method is adapted for use in private practice.

THE CLINICAL MANIFESTATIONS OF PRIMARY BRONCHIAL CARCINOMA *

ELMER H. FUNK, M.D.
PHILADELPHIA

This report is based on an analysis of the clinical features presented by sixty-one patients with primary carcinoma of the bronchus in whom the diagnosis was verified by histologic examination of tissue removed bronchoscopically (thirty-six cases), surgically (eight cases) or post mortem (twenty cases). In this group were fifty men and eleven women, a ratio of 4.5 men to 1 woman. The youngest patient was a woman, aged 24, and the oldest a man, aged 73. Only two patients were under 35 years of age (24 and 27). Twenty-seven patients (44.2 per cent) were between 35 and 45. The predominance among men, the incidence after the age of 35, and especially in the decade between 35 and 45, are factors of significance in diagnosis.

The increasing clinical interest in the early diagnosis of primary carcinoma of the lung has been stimulated by the recognition that origin from the larger bronchi occurs in the vast majority of cases, and, therefore, skilful bronchoscopy becomes, in selected cases, the most useful procedure in making a diagnosis.[1]

Weller[2] states that the type of carcinoma that occurs in the hilus, comprising perhaps 90 per cent of all cases of carcinoma of the lung, is practically always bronchiogenic.

The right side was involved in thirty-four and the left in twenty-six instances among the sixty-one patients in whom it was possible to locate the origin of the neoplasm with reasonable accuracy.

CLINICAL MANIFESTATIONS

No set description can be given, since the clinical picture varies greatly, depending on the following factors: (1) the location of the neoplasm and the rapidity of its growth; (2) the degree of bronchial obstruction produced; (3) the presence of secondary infection and suppuration; (4) the pressure on adjacent structures; (5) the occurrence of pleural involvement, which is not infrequently associated with effusion and, (6) the influence of local and general metastases. These factors in varying combinations produce many dissimilar clinical pictures, which may closely resemble other common and rare diseases of the respiratory tract.

The onset of symptoms is usually insidious but may be sudden with pain in the chest, pulmonary hemorrhage, dyspnea, or symptoms resembling an acute bronchitis. Among approximately one third of the patients the onset was not unlike an acute respiratory tract infection, the patient stating that the initial features were "a cold," "cough with fever," "a cough with pain in the side," "acute bronchitis" and "pneumonia." While the early symptoms are usually bronchial, many patients complain early of pain in the chest, which varies in severity from an indefinite discomfort to that resembling acute pleurisy. The relative frequency of the local symptoms in sixty-one patients was as follows: cough, 88 per cent; expectoration, 67 per cent; pain, 72 per cent; hemoptysis, 45 per cent; dyspnea, 50 per cent. The general symptoms of weakness and loss of weight follow, as a rule, the occurrence of the local symptoms and were sufficiently evident as to be noted as a part of the present illness by the patient in 80 per cent of the cases.

The cough does not present characteristic features. It usually occurs early and may be continuous but is not infrequently characterized by periods of improvement and aggravation which are attributed by the patients to attacks of bronchitis. It may be so severe as to interfere with sleep. Wheezing is common and has been mistaken for asthma. In the later stages with extension of the growth and pressure on surrounding structures the cough may resemble that of aortic aneurysm, which may be suspected, especially when hoarseness occurs as a result of involvement of the recurrent laryngeal nerve.

Hoarseness or huskiness of the voice was noted at the time of admission in five patients (8 per cent).

The expectoration may be absent, scant and mucoid, or profuse and purulent in character. Profuse and purulent sputum, suggestive of pulmonary suppuration, was present in one third of our patients. The "currant-jelly sputum" is rarely encountered, and I have seen no cases in which this type of sputum had any diagnostic significance. While careful search of the sputum has been stated in reported cases to reveal occasionally fragments of tumor tissue, I have not been able to make a diagnosis by this method in any of my patients. Tubercle bacilli were not found in any of the numerous specimens of sputum examined, and no evidence of clinically active tuberculosis was found to be associated with the new growth in the present series of patients.

Hemoptysis occurred in approximately one half of the patients. It may occur early or late and varies in amount from streaking of the sputum to frank hemorrhage. In some patients the frequent recurrence of bleeding produces a marked secondary anemia. A large fatal hemorrhage is rare. I cannot recall a death among my patients due to this cause.

[2] Weller, C. V.: Primary Carcinoma of the Lung, Arch. Path. **7**: 478 (March) 1929. This article contains an excellent bibliography

Mild dyspnea on exertion is common, the more marked forms occurring with bronchial occlusion, or complicating pleurisy with effusion. It may be the first or principal symptom, but more often it develops during the course and in association with other local symptoms. Cyanosis parallels the dyspnea and is explicable by the associated pulmonary complications; marked cyanosis is usually a late event in the disease.

Pain in the chest is not only a common but frequently an early complaint of the patient. In this series it was next in relative frequency to cough. The pain is variously located in the chest and is described as sharp or dull, intermittent or continuous, and tends to become worse as the disease progresses. Dysphagia is usually a late symptom.

The general symptoms, fever, weakness, loss of weight and pallor, are variable in their time of appearance. They usually occur late in the disease. Fever was present in 55 per cent of the sixty-one patients at some time while under observation. It is due to associated bronchitis, pulmonary suppuration, bronchiectasis, bronchopneumonia and pleurisy. The fever may be slight or marked with remissions and intermissions associated with chilliness and sweats. The latter occur especially with abscess formation. A rapid pulse is associated with the pyrexia. In the late stages, cachexia may be pronounced.

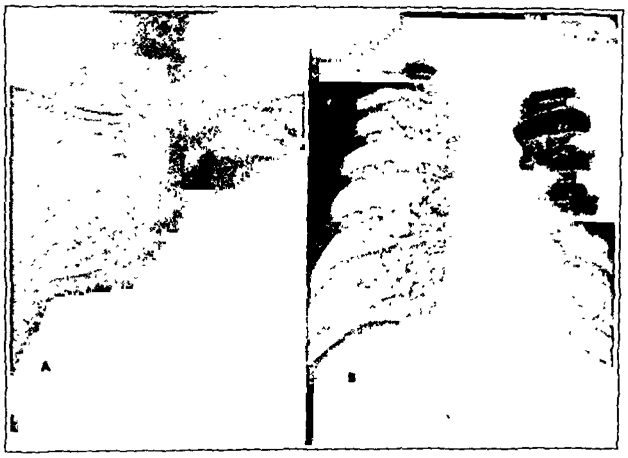

Fig. 1 (case 1).—*A*, obstructive atelectasis of the left lung due to neoplastic obstruction (complete) of the left main bronchus. *B*, expansion of the lung within forty-eight hours after the bronchoscopic removal of obstruction by Dr. L. H. Clerf. The signs of obstructive atelectasis were typical; the cause was not definitely known until the histologic examination of the bronchoscopically removed tissue revealed new growth. (These and the following roentgenograms are by W. F. Manges and J. T. Farrell, Jr.)

EXTRATHORACIC METASTASES

Numerous writers have discussed the frequency of metastases to the various organs, especially to the nervous system and skeleton. Any organ may be involved. An early and significant finding clinically is the metastases to the supraclavicular nodes, which, when small, may easily be overlooked. In most instances, in my experience among patients who came to the chest clinic, extrathoracic metastases were late phenomena. Distinct evidence of metastases to the nervous system was present in eight cases (cerebral six, spinal two), or 13 per cent, and to the abdominal organs in four cases of the group of sixty-one patients while in the hospital. There is an important group of patients in whom the extrathoracic metastases obscure the primary bronchiogenic carcinoma. In this connection may be quoted the report of Fried and Buckley,[3] who found central nervous system metastases in fifteen of thirty-seven patients with bronchiogenic cancer. In eleven of the fifteen patients a diagnosis of primary tumor of the brain was made and the bronchiogenic tumor was overlooked. An intracranial operation was performed in eleven patients and a metastatic tumor was removed in ten instances. Fried and Buckley state that when a person of middle age has an abrupt onset of symptoms and signs of a rapidly developing intracranial lesion, a metastatic cerebral lesion should be thought of and that the lungs are the most common site of the primary lesion. A metastasis to the brain may be mistaken not only for a rapidly growing glioma but also for a vascular lesion or an encephalitis.

Among four patients in the series with marked abdominal symptoms due to metastases, in two instances the abdominal symptoms preceded the occurrence of respiratory symptoms, and in one of these an abdominal operation had been performed before admission.

EFFECTS OF PRESSURE

The presence of dilated veins of the head and neck, upper extremities, and over the thorax and abdomen, of laryngeal paralysis, dysphagia and inequality of the radial pulses are usually late manifestations in the course of the disease.

THE PHYSICAL AND ROENTGEN OBSERVATIONS

There are no pathognomonic thoracic signs and those found are in varying combinations dependent on the influence of the various factors mentioned. There may be no abnormal physical observations. Usually, however, the early signs are those of bronchial irritation. Wheezing is common. Unilateral limitation of expansion is the most common sign. In most instances the signs are those of the associated pathologic conditions, bronchitis, obstructive atelectasis, obstructive emphysema, abscess, bronchiectasis, and pleurisy with or without effusion.

The roentgenologic evidence may be most valuable in determining the presence and location of the tumor, especially when the hilar mass is sufficiently large and not obscured by the many secondary pathologic changes that may occur in the lung and pleura (figs. 1 to 6). When these are present the roentgen picture may resemble numerous other pulmonary lesions.[4]

BRONCHOSCOPIC EXAMINATION

The diagnostic significance of the bronchoscopic observations has been described by Chevalier Jackson.[1] Briefly, it may be stated that this procedure, which represents the most recent and important advance in thoracic diagnosis, is the only method by which an early diagnosis of bronchial new growth can be made with reasonable certainty in the vast majority of patients. Without bronchoscopy, the diagnosis must often remain in doubt until extrathoracic metastases occur or tissues are removed at operation or at autopsy. Bronchoscopy has taught physicians to suspect new growth more frequently, especially in adults with obscure pulmonary lesions, particularly when the signs of bronchial obstruction are present.

DIAGNOSIS

The two essentials are (1) to recall the possibility of bronchiogenic carcinoma in adults with obscure pulmonary disease, and (2) to make a complete study, including a consideration of the history, physical signs, sputum, roentgenographic and bronchoscopic observations. There are certain conditions that cause confusion but a complete study should exclude them in the majority of cases.

Tuberculosis.—The chronic cough, expectoration, hemoptysis, fever and wasting are most frequently mistaken for tuberculosis, especially when the bronchiogenic cancer invades the upper lobe. Basal growths with the apexes clear cause less difficulty. The sputum studies are important, and it is a good rule to question the diagnosis of tuberculosis when in the presence of a persisting gross lesion the sputum contains no tubercle bacilli (fig. 5).

Bronchial Obstruction.—The recognition of the presence of bronchial obstruction and the associated lesions of atelectasis, emphysema, bronchiectasis and abscess are secondary in importance to the determination of the cause of the obstruction. Foreign bodies and aortic aneurysm may be recognized by the history, physical signs and roentgen observations. On the other hand, neoplastic obstruction, while frequently suspected in adults of the cancer age with pulmonary lesions of obscure etiology, may often fail to be recognized unless bronchoscopic studies are made (fig. 1). Benign new growths and obstruction due to inflammatory changes and cicatricial stenosis can be differentiated only by bronchoscopy. Aortic aneurysm should be excluded before bronchoscopy is done. Carcinoma of the esophagus, as a result of the overflow of its contents and pressure on or penetration into the air passages may give rise to distinct respiratory symptoms. In primary bronchial cancer the reverse process may produce esophageal symptoms. A careful study of the order of the appearance of symptoms and of the swallowing function and the roentgen and direct endoscopic examinations should establish the diagnosis. Tracheal cancer may give rise to symptoms not unlike those in bronchial involvement, and only by bronchoscopy can differentiation be made.

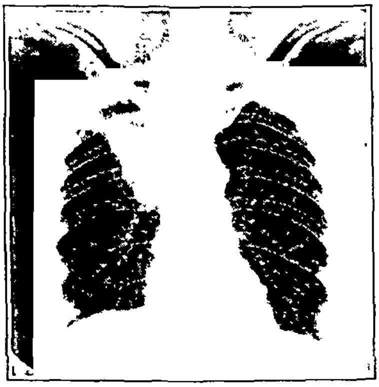

Fig. 2 (case 2).—Primary carcinoma of the bronchus. Nodular mass at the right hilus with atelectasis of upper portion of right lung due to bronchial obstruction by a neoplasm completely occluding the bronchial lumen.

Pulmonary Abscess.—The differentiation of noncarcinomatous from carcinomatous pulmonary abscess may present unusual difficulties. Several aspects of the problem involved are given in the brief case reports in the legend of figure 3. Generally speaking, a pulmonary abscess of obscure etiology occurring in a man past 30 or 35 should be suspected of a malignant origin. Bronchoscopy will usually settle the diagnosis. That errors may occur in spite of the most complete study is exemplified by the following patient: A man, aged 51, had been ill for one year with cough, increasing expectoration, dyspnea, huskiness of the voice, and loss of weight. The physical and roentgen observations indicated an extensive lesion in the lower portion of the right upper lobe. The fingers were clubbed. The roentgenogram showed a distinct large abscess cavity with a fluid level not unlike that shown in figure 3. No tubercle bacilli were found in the sputum. A bronchoscopic examination by Dr. L. H. Clerf revealed stenosis of the right bronchus, probably neoplastic, and a histologic study by Dr. B. L. Crawford revealed carcinoma. Autopsy revealed a primary carcinoma of the head of the pancreas with metastases to peribronchial nodes and to various other organs. The pulmonary abscess was secondary to a malignant bronchial obstruction, which in turn was secondary to the primary abdominal neoplasm. However, carcinomatous pulmonary abscess is associated in the vast majority of instances with primary rather than secondary neoplasms of the bronchus and lung.

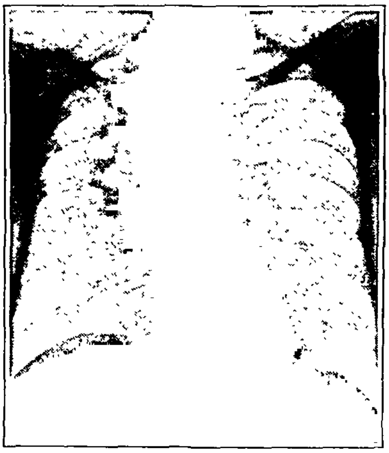

Fig. 3 (case 3).—Carcinomatous abscess, with a cavity presenting a fluid level in the right upper chest, in a man, aged 51, who had had a chronic cough with scant mucoid expectoration since he had had influenza twelve years before. Seven months before, a severe pulmonary hemorrhage occurred, and since then the cough had become more severe and productive of a fetid mucopurulent sputum. Other symptoms were pain in the right side of the chest, fever, weakness and loss of weight. The fingers were distinctly clubbed. The sputum showed no tubercle bacilli. The physical signs and roentgen observations on admission indicated an abscess with cavitation in the upper part of the right lung. The left lung was clear and there were no demonstrable extrathoracic lesions. Clinically and bronchoscopically, the condition was considered to be pulmonary abscess. At operation, Dr. J. B. Flick, suspecting new growth, removed a section of tissue which Dr. B. L. Crawford found to be a squamous-cell carcinoma. At autopsy a primary cancer of the bronchus (epithelioma), pulmonary abscess, local metastases, but no extrathoracic metastases were found. By contrast, another patient with a similar history and observations was not studied bronchoscopically because all the available evidence seemed to point clearly to a pulmonary abscess. At operation Dr. Flick suspected neoplasm and the tissue removed showed squamous-cell cancer. At autopsy the neoplasm was found to originate from the left main bronchus, and in retrospect it was evident that a positive preoperative diagnosis could have been made had a bronchoscopy been done.

Syphilis.—Pulmonary syphilis is rare, but it may simulate bronchopulmonary new growth. The history, atypical pulmonary signs, concomitant evidence of syphilis elsewhere, the positive Wassermann reaction and the therapeutic test are criteria useful in the diagnosis of pulmonary syphilis, which is usually made by exclusion. The two conditions may coexist, i. e., bronchial cancer and latent syphilis. Curiously, in the series of sixty-one patients the routine Wassermann test was positive in only two instances (fig. 6). Bronchoscopy will usually settle the differentiation between the two lesions.

Pneumonoconiosis.—Long exposure to inorganic dust may give rise to localized pulmonary changes which, on roentgen examination, may suggest an associated neoplasm (fig. 4).

Pleurisy.—The pleura is almost always involved at some time during the course of bronchiogenic cancer, and at autopsy metastatic pleural lesions are frequently found. Reference has been made to the frequency of pain in the chest, especially early in the disease. An exudative pleuritis, simple hemorrhagic or purulent, may mask clinically the underlying bronchiogenic neoplasm. Effusion was present in sixteen of the sixty-one patients (26.2 per cent); serous or serofibrinous in three, purulent in three, and hemorrhagic in ten. While the dulness and the distant breath sounds of atelectasis may, if the displacement phenomena are not carefully studied, mislead to a dry tap, it is important to remember that not infrequently effusion associated with bronchiogenic carcinoma does not cause distinct displacement of the heart and mediastinum to the opposite side. In other words, the presence of an effusion is often difficult to determine apart from a diagnostic pleural puncture. The laboratory examination of the fluid has not been helpful in diagnosis. The hemorrhagic character is suggestive. The careful clinical study, suggestive features such as an undetermined cause, persisting pain, dyspnea out of proportion to the pleural involvement, symptoms of associated and persistent bronchial irritation, atypical roentgen observations and a negative tuberculin test all suggest the need for complete diagnostic study which, when bronchoscopy is included, *may reveal the obscure bronchiogenic* cancer.

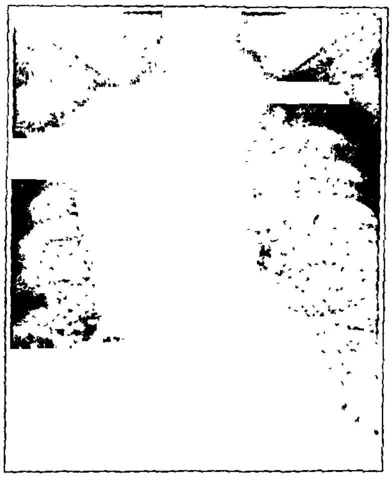

Fig. 4 (case 4).—Pneumonoconiosis and bronchial cancer in a miner, aged 38, who had had a "chronic bronchitis" for many years. Three months before he was seen the cough and expectoration increased and the sputum was blood tinged. For a long (?) period the patient had noted an increasing shortness of breath on exertion and an indefinitely located dull pain in the chest. The physical and roentgen observations indicated generalized pulmonary changes with a massive solid lesion in the right upper part of the chest. The trachea was displaced to the right. The sputum showed no tubercle bacilli. The tentative diagnosis was pneumonoconiosis with either localized fibrosis or atelectasis of the right upper lobe due to bronchial obstruction. On bronchoscopic examination Dr. L. H. Clerf found an obstructing neoplasm and a removed section of tissue revealed a primary bronchial carcinoma. Subsequently extrathoracic metastases and death occurred.

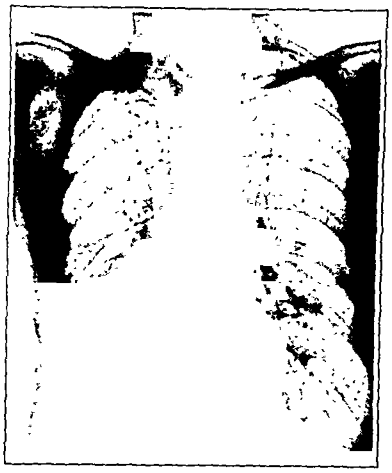

Fig. 5 (case 5).—Bronchial epithelioma in a man, aged 67, who had been ill one year, the onset following "pneumonia," which lasted one month (?). He was subsequently treated for tuberculosis. Cough, expectoration, hemoptysis, pain in the chest and shortness of breath were the local symptoms. Fever was present at the onset and at intervals, and a loss of 35 pounds (16 Kg.) occurred during the year. Sputum examination showed no tubercle bacilli. The physical and roentgen observations indicated a gross lesion in the lower right part of the chest. These suggested fibrosis of the lung with pleural thickening and contraction. There was no evidence of extrathoracic lesions. The left lung was clear. A tentative clinical diagnosis of pulmonary fibrosis and bronchiectasis was made and the patient referred to Dr. L. H. Clerf for bronchoscopic study. A section of tissue was removed bronchoscopically from the right lower lobe bronchus and the histologic examination showed a squamous-cell carcinoma (B. L. Crawford).

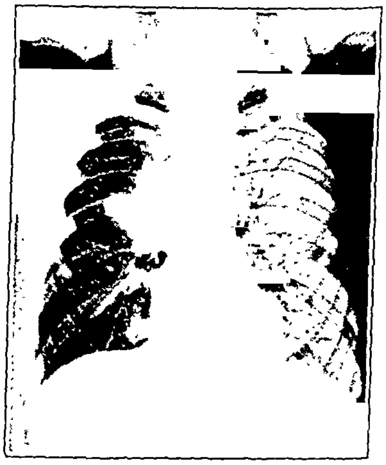

Fig. 6 (case 6).—Primary cancer of the right bronchus in a man, aged 41, who had previously been in good health except for recurring bronchitis, and had noticed two weeks before admission a distinct and persisting pain in the right part of the back. Shortly afterward cough, expectoration, shortness of breath on exertion, and weakness with a loss of 15 pounds (6.8 Kg.) developed. The examination on admission showed distinct limitation of motion in the right side of the chest, diminished breath sounds in the lower right part of the chest, and the generalized signs of bronchitis. The roentgenogram revealed a mass in the region of the right hilus. There were no extrathoracic lesions. The Wassermann and Kahn reactions were positive. Pulmonary syphilis and new growth were diagnostic possibilities. A bronchoscopic examination by Dr. L. H. Clerf revealed a neoplasm of the right bronchus, and a section removed for microscopic study by Dr. B. L. Crawford showed carcinoma.

Miscellaneous.—Not only the common but the rare thoracic diseases, for example, the various mycoses, may at times require differentiation from bronchiogenic carcinoma.

PROGNOSIS

Among twenty patients coming to autopsy, death occurred within one year from the onset of the symptoms in eleven instances, and within one and a half years in all except three instances. Among some of the patients, and especially among those given roentgen therapy, the duration has been much longer, one patient remaining well after six years. This patient is an exception to the generally fatal outcome within a relatively short period of time.

It is to be hoped, since early diagnosis has now become possible through the aid of the bronchoscopist and the pathologist, that the advances in thoracic surgery or the development of a more satisfactory cancer therapy *may render prognosis less unfavorable* than it is at present.

SUBTOTAL GASTRECTOMY FOR DUODENAL ULCER

TEN YEARS' EXPERIENCE AND CLINICAL END-RESULTS [*]

ALFRED A. STRAUSS, M.D.
LEON BLOCH, M.D.; J. C. FRIEDMAN, M.D.
JACOB MEYER, M.D.
AND
MORRIS L. PARKER, M.D.
CHICAGO

This study is based on the results of 221 subtotal gastrectomies for duodenal ulcer, and represents the combined opinions of a stomach study group composed of surgeons, internists, roentgenologists, pathologists, research fellows, and a member of the social service department. The social service department was added for the purpose of studying the economic conditions of peptic ulcer patients before and after medical treatment, as well as before and after operation. All patients were admitted, not as medical or surgical, but for the stomach group to dispose of, depending on the facts disclosed by the group study. At first there were differences of opinion as to the disposition of these cases, but as we learned from our experience, these differences disappeared. Of late years there has been little question as to whether a patient should be continued on medical treatment or should be operated on.

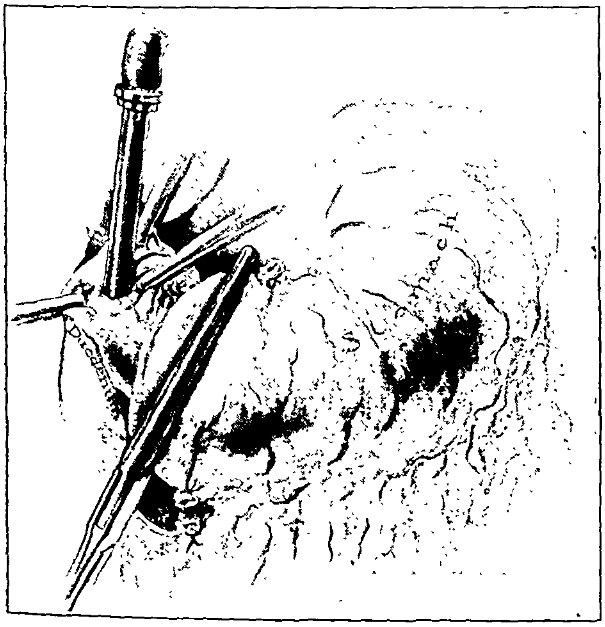

Fig. 1.—After the blood vessels have been divided and ligated in the region of the pylorus and duodenum, the anterior duodenal wall has been opened and the duodenal contents are being aspirated by suction.

We have taken the point of view that all chronic gastric ulcers should be treated surgically and never medically for the following reasons: There is not a known means of telling whether a gastric lesion is an ulcer or a beginning carcinoma until serial sections are studied microscopically. Until some one discovers a serologic test for carcinoma, such as there is for syphilis, we feel that these lesions are definitely surgical. To this we must add associated factors of fatal or near fatal hemorrhage and penetration into the pancreas and lesser peritoneal cavity, with their most severe symptoms and bad results. Finally, a comparison of the clinical end-results and mortality of medical treatment with from 5 to 9 per cent mortality from subtotal gastrectomy brings the argument all in favor of surgery.

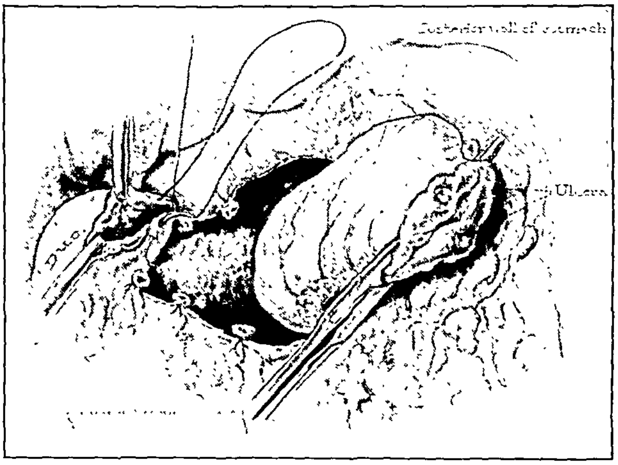

Fig. 2.—The duodenum has been cut through beyond the ulcer and is being closed with a silk suture, the Connell stitch being used.

DUODENAL ULCER

Our attitude toward the type of therapy for duodenal ulcer is quite different, first, because of the extreme rarity of carcinoma of the duodenum, and, secondly, because of the spontaneous tendency of the ulcers on the anterior wall of the duodenum to heal.

We feel that every duodenal ulcer should have the benefit of at least one thorough medical treatment, irrespective of the patient's economic condition. How long this should be continued and how often such medical treatment should be repeated depends on the symptoms he has after medical treatment, the patient's economic condition, and the character of the lesion as shown by a roentgenogram portraying a cloverleaf deformity.

Our experience has been that in all cases in which the ulcer is not bleeding or perforating, the patients are usually relieved of their symptoms after two weeks' rest in bed, and the usually accepted routine medical management. We have come to the conclusion that the most important factors in medical therapy are rest in bed and relief from the stress, strain and worry that come in daily life. The majority of the patients who come to the hospital, who have never had medical treatment and who are relieved at the end of two weeks, do not want surgery and usually decide to go home. We attempt to follow these cases in the outpatient department. Those who have had two or more treatments in our group or at other medical clinics know that this relief is only temporary, and usually prefer surgery to repeated medical treatments. For the ordinary wage earners who have had a thorough medical treatment and who have a return of symptoms, so that they are unable to earn a living, we advise operation rather than further medical management. We have learned from our social service department that by far the largest number of such patients, in order to undertake a second medical treatment, would need the assistance of their relatives or charitable organizations to take care of the dependent members of their family. This is another factor that influences us to suggest surgery. On the other hand, if the patient is wealthy and the ulcer is not complicated, we feel that he can have as many treatments as he desires, always informing the patient of the possibility of a fatal hemorrhage or perforation. If the roentgen examination shows a clover-leaf deformity, little can be expected from medical treatment. While we willingly give the patient the benefit of such treatment, we do not hesitate to tell him that the chances for cure by medical management, for any length of time, with such a lesion, are practically nil. The reason is that the majority of clover-leaf deformities of the duodenum are due to an ulcer on the posterior duodenal wall, penetrating into and adhering to the pancreas. This penetration produces contraction of the duodenum, the surrounding mesentery, hepatoduodenal ligament, and capsule of the pancreas with resulting dilatation, formation of diverticula and deformity of the duodenum about the point of contraction, thus explaining the clover-leaf deformity as seen in roentgenograms and at operation.

---

[*] From the Julius Rosenwald grant to the Stomach Group of the Michael Reese Hospital. The organization of the Stomach Group is as follows: Alfred A. Strauss, M.D., Ralph B. Bettman, M.D., Morris L. Parker, M.D., and Bernard Portis, M.D., surgery; Leon Bloch, M.D., J. C. Friedman, M.D., and Jacob Meyer, M.D., medicine; William Thalhimer, M.D., and Otto Saphir, M.D., pathology; and Robert A. Arens, M.D., roentgenology.

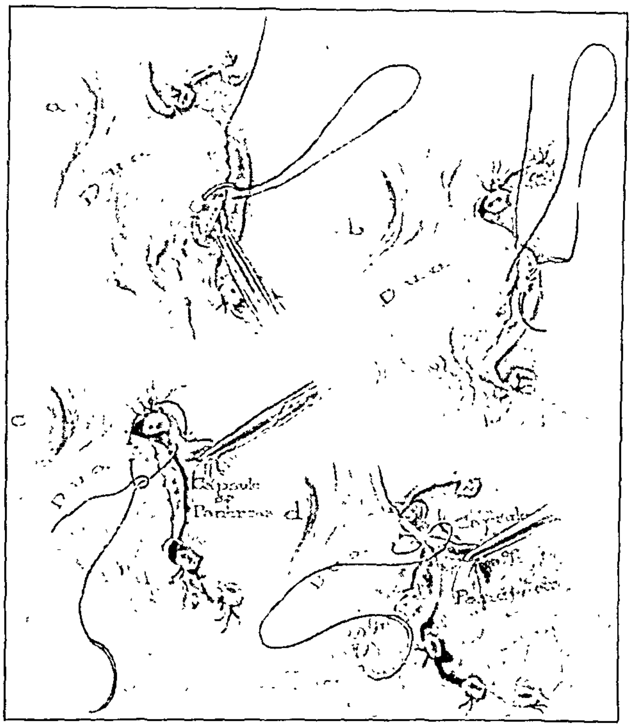

Fig. 3.—The duodenal stump is closed with two rows of silk sutures, first a Connell and then a Cushing stitch being used. The suture line is then covered with the capsule of the pancreas.

Our experience has been that these ulcers on the posterior wall do not heal, and for this reason we give the foregoing prognosis concerning medical treatment in such cases. These patients suffer not only from the ulcer that is present but also from the mechanical difficulty that the stomach has in forcing the food through the contracted duodenum.

In young patients who give a history of severe hemorrhage and come in with a second hemorrhage, we advise immediate blood transfusion. If bleeding stops, a subtotal gastrectomy in from ten to fourteen days is indicated. A second blood transfusion is given just before operation, if conditions warrant, and a third, if necessary, immediately after. Older patients, from 50 to 70 years of age, who come in with a severe hemorrhage usually do not stop bleeding, because of a more or less advanced arteriosclerosis. A large percentage of these patients need an operation within from twelve to twenty-four hours, preceded and followed by blood transfusion. Patients who have acute symptoms of perforation we have tried to keep on medical management from ten to fourteen days after the acute symptoms have subsided, and then subtotal gastrectomy is indicated. Those who have retention from anatomic obstruction we also try to hold from ten to fourteen days, aspirating the stomach dry several times daily. This decreases the size of the stomach and relieves the inflammatory process in the duodenum and stomach wall. During this time the patients are flooded with saline solution and dextrose subcutaneously, and a blood transfusion is given just before operation.

The social service department reports that a large number of these patients, even before medical treatment, are on a 50 per cent earning basis and between medical treatments 50 per cent of them are on a half time working basis. Of those patients who have had several medical treatments when coming to operation, 65 per cent have not been able to work at all. The types of occupation that our patients are engaged in may be classified as moderately hard labor as they are chiefly bakers, tailors, small shopkeepers and pedlers. Patients who have been treated by subtotal gastrectomy are on

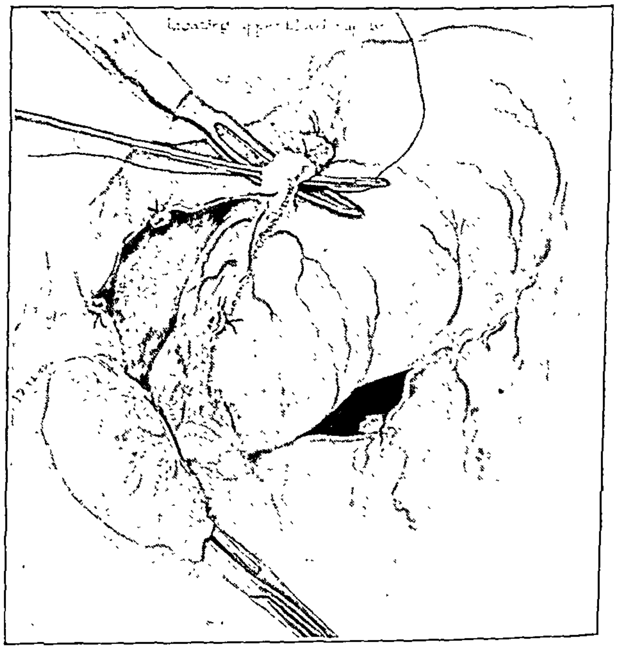

Fig. 4.—After the omentum has been separated from the greater curvature of the stomach until about 60 per cent of it is free, the blood supply on the lesser curvature is ligated three times at the re-entrant angle and divided between the second and the lower suture.

a full time working basis in from four to six months in 95 per cent of the cases.

Pathology.—The pathologic changes in living tissue as seen at operation are as follows: On opening the abdomen and lifting the duodenum into view, one usually sees punctiform hemorrhages on the anterior wall similar to the conjunctival injection as caused by a cinder in the eye. The punctiform hemorrhage is pathognomonic of duodenal ulcers and occurs by simply exposing the duodenum to the air. On further irritating this area with the gloved hand or sponge, it becomes more marked. This is due to the increased vascularity produced by the chronic duodenitis. We feel so positive about this punctiform hemorrhage that without it we doubt the presence of an ulcer. If a clover-leaf deformity is present in the roentgenogram one can see the corresponding deformity clearly in the duodenum. There is usually a contraction, and one or two diverticula above the contraction. On opening the lesser peritoneal cavity and placing the index finger along the posterior wall of the stomach and duodenum, one usually finds the lesser peritoneal cavity more or less obliterated, because of adhesions about the lower third of the posterior wall of the stomach, the mesocolon, and the capsule of the pancreas. The head of the pancreas is harder than normal and tightly adherent to the pyloric ring or first portion of the duodenum. The latter condition always means ulcer of the posterior wall penetrating into the head of the pancreas. The surrounding peritoneum of the duodenum and the hepatoduodenal ligament are adherent and markedly thickened as the result of the existing inflammatory process. The periduodenal peritoneum sometimes becomes very thick and peels like a banana. The stomach wall is thickened in its lower third and sometimes its lower half, and if the deformity of the duodenum is very severe the stomach is usually hypertrophied and edematous in appearance, giving a clinical picture of subacute and chronic gastritis. We have found that more than 70 per cent of our patients operated on have a penetrating ulcer of the posterior wall.

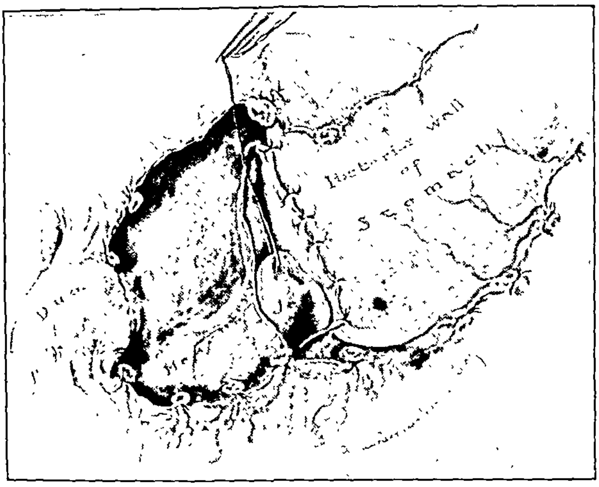

Fig. 5.—After the transverse mesocolon has been split to the left of the middle colic artery, the left leaf of it has been sutured to the posterior wall of the stomach. The jejunum is being brought through the slit.

In addition to the marked and severe duodenal ulcer there is often associated a cholecystitis and pancreatitis, aside from gallstones.

Keeping the foregoing pathologic conditions in mind, we have formulated the two following basic laws for the successful surgical treatment of ulcers:

1. That all pathologic tissue should be removed. This includes the first portion of the duodenum and the lower half of the stomach.
2. That the stomach must have a rapid or quicker than normal emptying time.

The clinical end-results are in direct proportion to the fulfilment of these two laws. Subtotal gastrectomy is the only operation that fulfils these laws; namely, it removes the pathologic conditions and usually gives the stomach an emptying time of from thirty to fifty minutes, which we think is ideal.

We have noted that if too small an amount of stomach (only the lower third) is removed, the stomach does not empty very rapidly. The same may be said when too much (from 75 to 80 per cent) is removed. After observing quite a large number of cases of low and high gastrectomies, we found that when about 60 per cent of the stomach is removed the stomach empties most quickly and best. This is due to the fact that the highly peristaltic portion of the stomach is removed, which allows only small portions of food to pass on at a time. The upper portion of the stomach has a more uniform constant contraction, keeping up a more constant intragastric tension, thus forcing the food into the jejunum like squeezing water from a sponge.

For those who object to the removal of the lower 60 per cent of the stomach for duodenal ulcer and agree that this is the proper operation for gastric ulcer, we answer that there is nothing of vital importance in the physiologic function of the first portion of the duodenum. If the principle of partial gastrectomy is correct for gastric ulcer it must be doubly correct for duodenal ulcer. The latter produces the greatest number of symptoms and the largest amount of irritability in the stomach. It can easily be compared to a patient who needs an amputation of his foot through the ankle joint. Most surgeons surely will amputate higher and sacrifice the lower third of the leg so as to insure the patient a better function with an artificial leg. We admit that the lower third of the leg is quite normal, but the patient

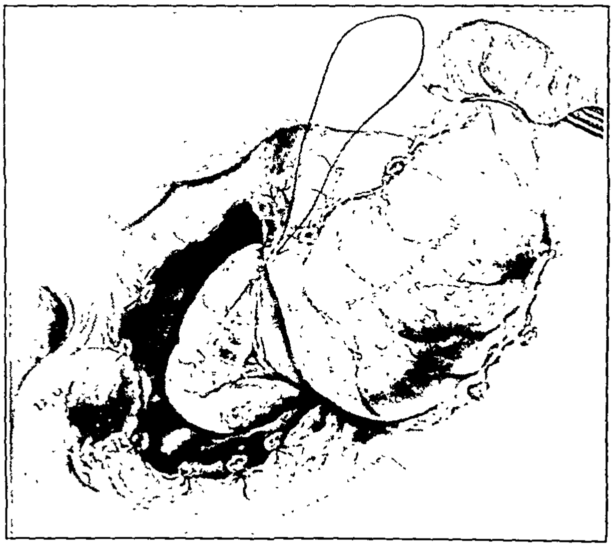

Fig. 6.—First row of posterior wall sutures being applied: Anastomosis of jejunum is begun about 5 inches beyond the ligament of Treitz, the proximal end being placed at the lesser curvature.

can walk much better with the higher amputation. So we feel quite certain, from our experience, that the patient can eat much better with one half of a stomach, from which all the pathologic tissue has been removed, than with a whole stomach in which a marked duodenal ulcer is present.

In subtotal gastrectomy, when the stomach does not empty quickly, the patient is apt to have symptoms such as he would have had from an unsuccessful gastro-enterostomy, while if the stomach empties in from thirty to fifty minutes the patient is usually symptom free. The various pyloroplasties, such as the Finney, Judd, Balfour, Horsley and Heineke-Mikulicz types, remove the anterior wall ulcer but do not affect the most important lesion, which is the ulcer on the posterior wall. This operation does not remove all of the pathologic condition, and again sends the physiologic processes of digestion through the inflamed duodenum and keeps the inflammatory process, as well as the associated cholecystitis and pancreatitis, active. A well functioning gastro-enterostomy sends the physiologic processes of digestion, most of the time, through the left portion of the stomach and puts the right side, the duodenum, gallbladder and pancreas, at rest. In most instances it would be a satisfactory operation, if it did not produce gastrojejunal ulcer, a much more serious lesion than the original duodenal ulcer.

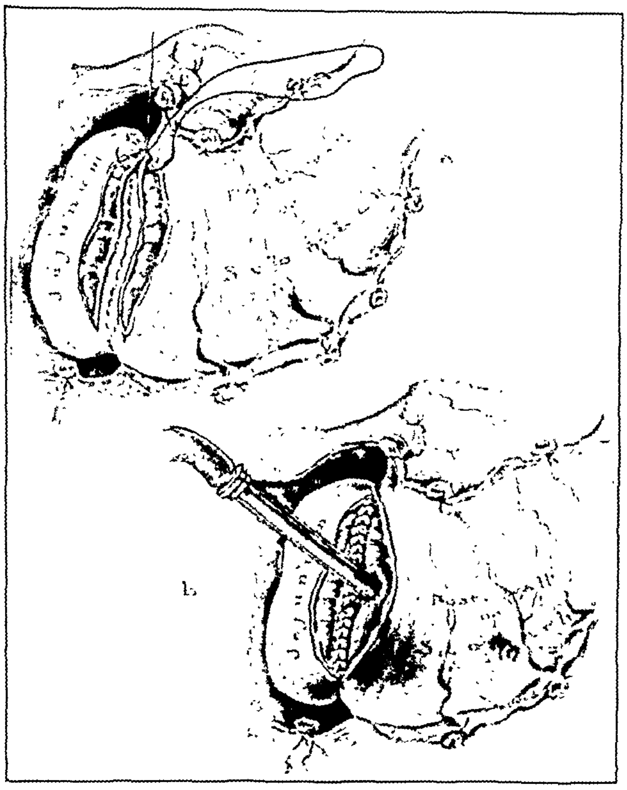

Fig. 7.—*a*, second row of posterior wall sutures is begun, muscularis being sewed to muscularis; *b*, mucosa of stomach incised and gastric contents aspirated.

Gastro-enterostomy should not be performed in acute duodenal perforation, since we have learned that a large number of these patients develop gastrojejunal ulcers, which seem to be more prevalent in this type of case than in any other. We have found this to be true not only in our own cases of this type but also in the cases in which operations were performed in other clinics. If a simple closure of the perforation is done, a large percentage of patients come back with an extensive penetrating ulcer, obstructive in character. Gastrectomy is not to be thought of, in our judgment, in the presence of an acute perforation. We prefer to do a simple excision of the ulcer and infiltrated area with the anterior portion of the pyloric ring, leaving the posterior wall of the stomach and duodenum intact, closing the resulting defect after the method of Judd or Horsley. This removes the pyloric sphincter, leaving a large opening at the point of anastomosis, and the results have been highly satisfactory.

The question now arises as to how often gastrojejunal ulcer occurs following gastro-enterostomy. It is difficult to get an accurate percentage of the occurrence of gastrojejunal ulcers, as it must be admitted that, in addition to the known number of such cases, some gastro-enterostomized patients, with symptoms, who are having medical treatment, are actually suffering from a gastrojejunal lesion. The percentage of gastrojejunal ulcers as reported from various clinics is: Berg and Lewisohn, 33 per cent; Bier's clinic, 28 per cent; Payr's clinic, 30 per cent; Hochenegg's clinic, 22 per cent; von Haberer, 16 per cent; Bastianelli, 25 per cent. It can readily be seen from these reports from various nations that there is little national or racial predisposition to the occurrence of gastrojejunal ulcer. Conservatively, the percentage of recurrences following gastro-enterostomy must be somewhere between 10 and 20 per cent.

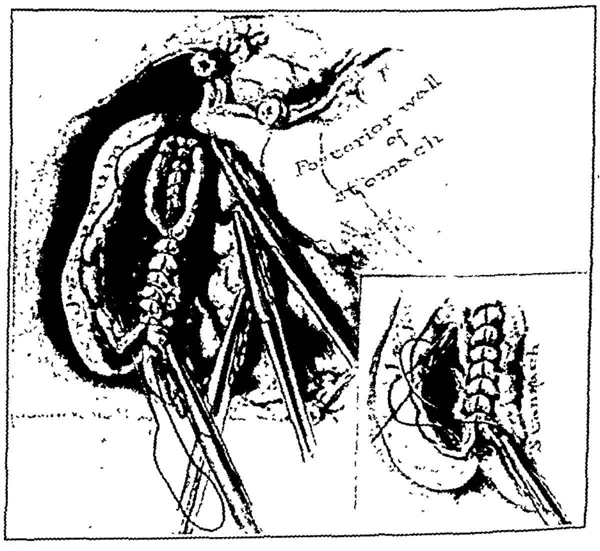

Fig. 8.—Third row of posterior wall sutures is applied, beginning at the middle, and is continued to the greater and lesser curvatures, an interlocking stitch being used.

We feel that the mortality and end-results of multiple operations for gastrojejunal ulcer plus the original mortality of gastro-enterostomy is greater than the mortality of subtotal gastrectomy, and the clinical end-results are far better in the latter operation. We therefore have come to the conclusion, in our stomach study group, that when surgery is indicated, with few exceptions we prefer subtotal gastrectomy or no operation at all. We would rather continue the patient on medical treatment than to subject him to a major operation that will give him a gastrojejunal ulcer, at least one out of every ten times, or to a pyloroplasty which will give him only partial relief from his symptoms. We have reserved gastro-enterostomy as a surgical measure for tuberculous patients and others with severe pathologic changes in the lungs, because in a large number of these cases a fulminating tuberculosis or embolic pneumonia will develop if gastrectomy is performed. During this ten year period we have performed only twenty-nine gastro-enterostomies for duodenal ulcer where pulmonary disorders were present.

Early in our experience in cases in which a marked cholecystitis and pancreatitis were present, we preferred cholecystectomy and a common duct drainage and left the ulcer alone, only to have to do, later, a subtotal gastrectomy. Later we performed cholecystectomy and gastro-enterostomy in six such cases; three of these patients came back with a gastrojejunal ulcer. At a later time we operated in six cases in which we did a cholecystectomy and subtotal gastrectomy for ulcer at the same sitting. Though we had no mortality in these six cases, we found in doing so much surgery at one time that the postoperative course was too stormy, making the risk too great. We finally decided, in this type of case, in which a cholecystitis and ulcer were present, to do a subtotal gastrectomy only and not interfere with the gallbladder. We have noted that in practically all these cases in which no stones were present the patients became free from their gallbladder symptoms after subtotal gastrectomy. This can easily be explained by the fact that in gastrectomy the duodenum is closed off. The physiologic process of digestion is sent down the left side, stopping the irritation of digestion in the duodenum, gallbladder and pancreas, thus allowing the mild infection in these two remaining organs, namely, the gallbladder and pancreas, to subside.

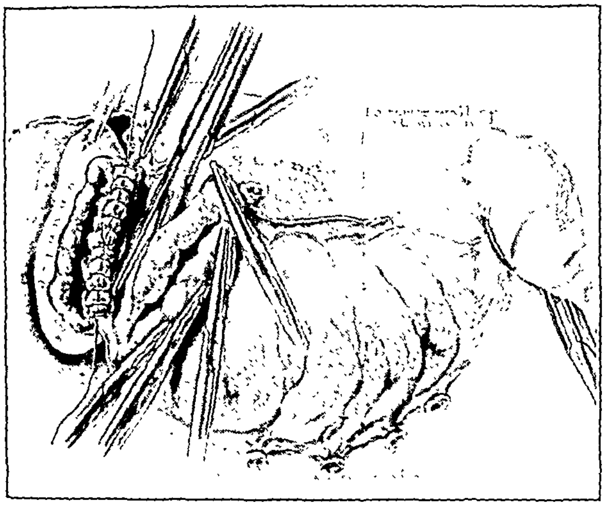

Fig. 9.—The stomach is now amputated from the anterior wall. All bleeding points are clamped and ligated.

As to the relationship of the appendix to duodenal ulcer, we have never removed the appendix in subtotal gastrectomy. In only two cases did we have to operate later for a subacute appendicitis. This would lead us to infer that the appendix plays only a minor rôle in the causation or aggravation of duodenal ulcer.

Surgical Technic.—In doing a subtotal gastrectomy we use a no-clamp method of the Polyá type.

Postoperative Complications.—Pneumonia and atelectasis are the most important and the most serious complications with which we have to deal. They often are noticed in the first twenty-four hours as an embolic process or a collapse of the lung, with high temperature, rapid pulse and rapid respirations. Cases of pulmonary infarcts occur also within twenty-four hours after operation. In our 221 cases, we had 26 cases of pneumonia, of which 13 were of a very mild type, lasting only about one to two days and, no doubt, of an atelectatic nature. Of the remaining 13 cases 5 ended fatally.

Symptoms of regurgitation that were not due to mechanical obstruction occurred in fourteen cases. These symptoms we believe are probably due to a disturbance in the neuromuscular mechanism. This condition usually corrects itself in about four days. A Rehfuss tube is passed into the stomach, through which the stomach is aspirated every two hours. If no more than from 60 to 90 cc. is aspirated each time, one can be sure that some of the secretions are passing through the stoma. At the end of forty-eight hours we inject through this tube 2 ounces (60 cc.) of water every hour, and aspirate every two hours. If there is less returned than the amount injected, one can be certain that this is not a mechanical obstruction and that it will correct itself. In four cases these symptoms persisted up to the third week, but at the end of ten days fluoroscopic examination revealed that some of the barium was passing through. One could infer that this disturbance was neuromuscular in origin. All of these cases were normal between the third and fourth weeks. One might be quite apt to mistake this condition for a mechanical obstruction. We are sure that two cases in which we reoperated at the end of ten days were of this type and were not mechanical, for little was found to account for the obstruction.

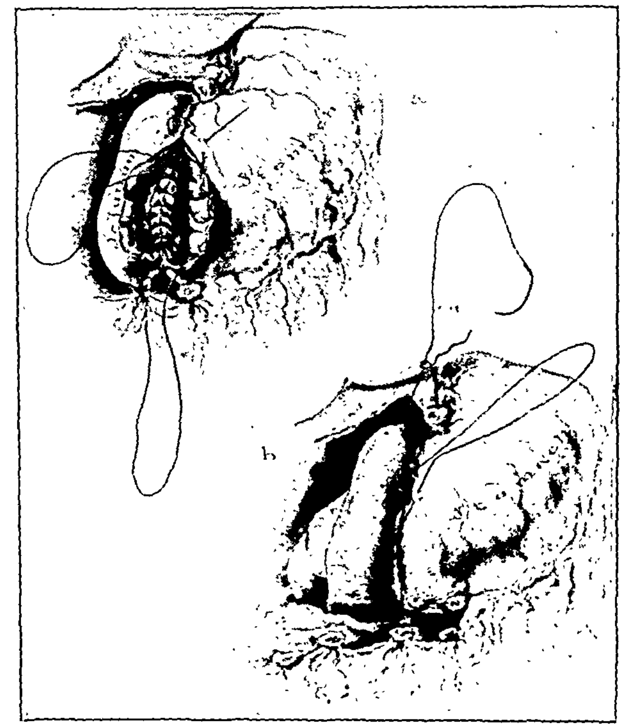

Fig. 10.—*a*, a continuous over and over suture is used to close the anterior wall; *b*, a seroserous Cushing stitch on the anterior wall complete the anastomosis.

True mechanical obstruction of the outlet of the anastomosis has not been common. We have found it in four cases, in three of which recovery took place.

However, one of the patients who recovered from the obstruction died two months later of an acute fulminating pulmonary tuberculosis. These obstructions at the outlet of the stomach are never an emergency as long as a Rehfuss tube is kept in the stomach. It is best to give the patient saline solution and dextrose subcutaneously, plus a blood transfusion for food value, until about the tenth day, when intervention should be considered. Usually the efferent loop of the anastomosis is mildly obstructed, owing to an exudate or constriction by a small piece of omentum which can be released easily. In order to insure the patient's future feedings, a Rehfuss tube with a wire is passed by mouth into the stomach and guided by the operator through the anastomosis to three or four feet *below the outlet* of the stomach. The patient then can be fed immediately and in a few days he can take food by mouth. If it passes through, the tube can be left in for several days longer and then removed in perfect safety.

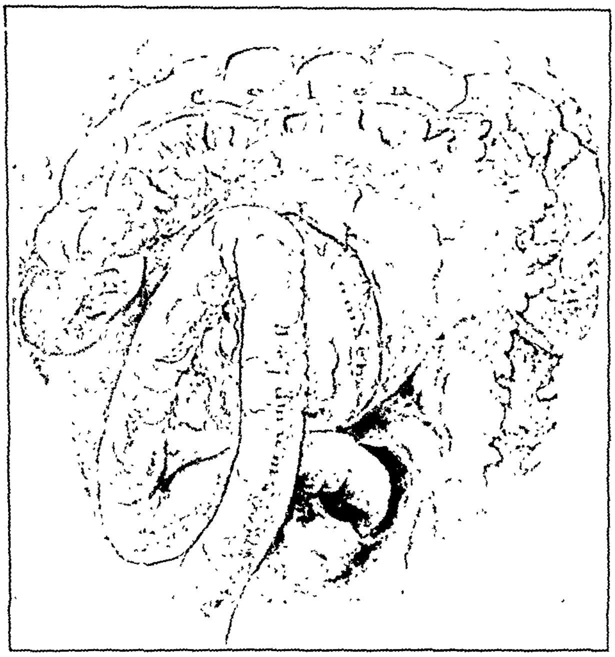

Fig. 11.—Right half of mesocolon is sutured to anterior wall of stomach, high above the anastomosis, and shows stomach and anastomosis well below mesocolon.

Peritonitis has been an extremely rare complication in our series. One case was due to a perforation following a phlegmon of the gastrectomized stomach. The second was a peritonitis deformans in which several operations were done in an attempt to relieve the obstruction.

We have had one case of cerebral hemorrhage with right hemiplegia.

We have had no cases of fatal pulmonary embolism.

We have seen only one subdiaphragmatic abscess associated with empyema in this series.

One patient developed an abscess in the lung and died four and one-half months after operation.

In the first fifteen cases of our series in which a low resection was performed there were two gastrojejunal ulcers which were later reoperated on; a high subtotal gastrectomy was done, and both patients made an uneventful recovery.

Mortality.—We have done 221 gastrectomies for duodenal ulcer, with 12 deaths, a mortality of 5.4 per cent. An analysis of this mortality shows that five patients died of pneumonia; one of a secondary perforation due to phlegmon of the stomach; one as the result of a subdiaphragmatic abscess with empyema; one from acute fulminating pulmonary tuberculosis two months after operation; one from cerebral hemorrhage with right hemiplegia, and one from coronary sclerosis with angina pectoris. This patient had anginal attacks previous to the operation, but they were not recognized as such until twenty-four hours before death. The observations were confirmed by autopsy. One patient died from peritonitis deformans following repeated operations to relieve the obstruction; one died of a lung abscess four and one-half months after operation. The case of coronary sclerosis with anginal attacks and the case of abscess of the lung four and one-half months after operation are included, but their relationship to the mortality following subtotal gastrectomy is certainly questionable.

In reporting this series of 221 cases, with a mortality of 5.4 per cent, 56 cases have been included in which operations had been performed previously and subtotal gastrectomy was the second or third operation. Forty-two cases were complicated by severe hemorrhage just before entering the hospital, or just after admission. Fifteen patients had acute penetrating symptoms within a short time before operation.

Clinical End-Results.—In following up these cases, we have found that 95 per cent are free from symptoms, are on no particular diet or medication, and have gained from 15 to 50 pounds. Some of these, a very small percentage, complained for from three to six months of fulness after eating, sweating and weakness, which appeared after each meal and lasted from ten to thirty minutes. This condition disappeared in from three to six months. We believe that this is a vagus disturbance and have noted it mostly in women who tend to be neurotic. In a number of cases in which these symptoms appeared the stomach emptied rather slowly and when the symptoms disappeared the emptying time was from thirty to fifty minutes. In the remaining

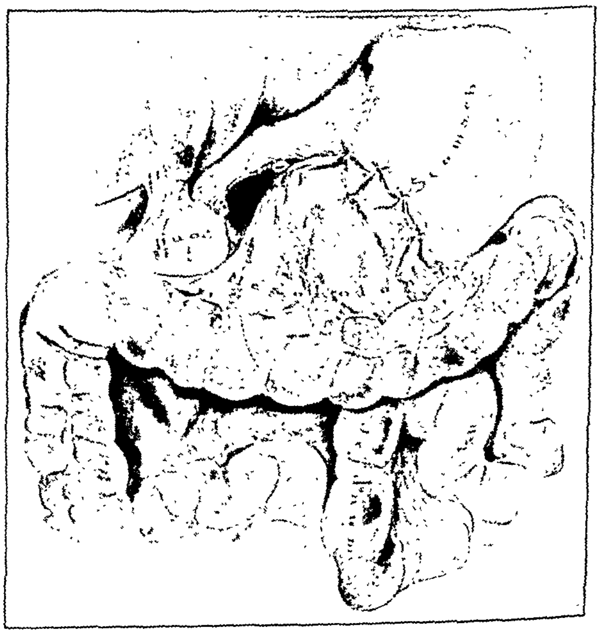

Fig. 12.—Appearance following completion of operation, showing the inverted stump of the duodenum, and the anastomosis below the transverse mesocolon.

5 per cent of cases there are symptoms of distress that cannot be accounted for by the emptying time or roentgenologic observations. Some of these were diagnosed as spastic colitis, others on the basis of a visceral neurosis. They usually occur in highly neurotic persons who do not gain in weight and in whom it is difficult to estimate how many of the symptoms are truly physical.

Emptying time was from one to one and one-half hours immediately after operation, but from three to six months afterward it was somewhere between thirty and fifty minutes. This shows that the stomach and jejunum undergo muscular development as the result of their new mechanical function and physiologic condition.

The acidity following gastrectomy corresponds with that published by Berg and Lewisohn. At the end of two weeks there was in 5 per cent of these cases a free acid of from 10 to 15, with a total acidity of from 25 to 30. In the remaining 95 per cent there was no free acid and the total acidity was from 5 to 10. In subsequent follow-up work on these cases there was no change from the immediate postoperative analyses. We believe that one great factor in this anacidity is the rapid emptying time of the stomach which prevents a reflex irritation and formation of hydrochloric acid.

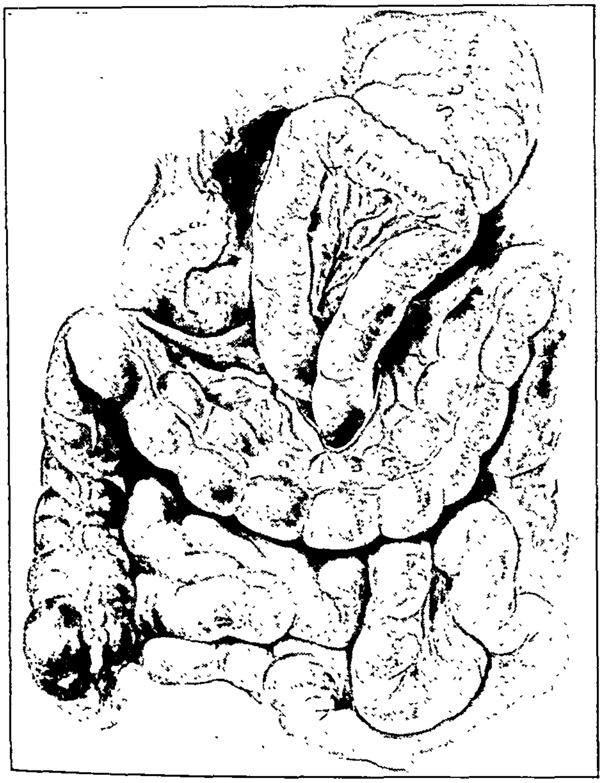

Fig. 13.—In cases of high gastric resection in which the mesocolon cannot be brought up to the stomach, the jejunum is brought through the slit and the mesocolon is left without being sutured.

There has been practically no change in the postoperative observations of the blood over the preoperative ones. Both hemoglobin and red blood cell count have remained the same or slightly higher. There were only two exceptions, one in a patient with a chronic bleeding ulcer who remained anemic, and the second in a patient with a severe diarrhea before operation which persisted after operation. Since then the diarrhea has stopped and the blood picture has become normal.

CONCLUSIONS

1. We believe that ordinary wage earners of the laboring class with marked recurring symptoms of duodenal ulcer should be operated on after one thorough medical treatment.

14. Our clinical end-results, as well as our 5.4 per cent mortality, in these 221 gastrectomies, which included complicated cases and those in which previous gastric operations were done, justify our continuance of this operation for duodenal ulcer in preference to any other surgical procedure.

THE INCIDENCE OF HEMORRHAGE IN PERFORATED GASTRIC AND DUODENAL ULCERS *

MOSES BEHREND, M.D.
PHILADELPHIA

PROTOCOL.—*Perforated ulcers rarely bleed.*
Bleeding ulcers rarely perforate.

Ulcers of the stomach and duodenum manifest themselves in various ways. They are selective in their location, their time of perforation and their incidence of hemorrhage. The varying degrees of morbidity caused by them depend to a large degree on their location. In searching for ulcers, physicians know from previous experience that the most likely site for their formation is the stomach and duodenum. Particularly are they prevalent along the lesser curvature of the stomach, the pylorus and the first portion of the duodenum. Ulcers that perforate are usually found in these places, but those that produce hemorrhage have not always the definite locations referred to. The reasons for these variations in the genesis of ulcers have never been definitely determined. Again, the fact that some ulcers may exist for years and never perforate or produce hemorrhage, but simply result in chronic invalidism, has never been satisfactorily explained.

For some time anatomists and surgeons have ascertained that certain areas around the pylorus possess a deficient circulation. These areas are immediately proximal and distal to the pylorus on the cephalad side. Naturally, the circulation varies somewhat in every patient, but generally there is an anemic area which is very noticeable when compared to the remainder of the stomach. In these bloodless areas perforations are quite apt to occur, which may account for the observation already made that perforated ulcers rarely bleed. I have never experienced such a case. I have also never had a perforation occur on the caudal surface of the pylorus, where the stomach is more richly supplied with blood (fig. 1). The cardiac end of the stomach and the posterior wall have also been more or less free from perforative ulcers. If perforation occurs in ulcers on the posterior wall of the stomach, they become adherent to the parietal peritoneum and the pancreas; the same may be said of perforating ulcers on the posterior wall of the duodenum.

Lately, independent of the work of Einhorn [1] and of Cole,[2] I conducted some research work concerning the blood supply of the stomach, especially at the pylorus. Immediately after a postmortem, the vessels supplying the stomach are clamped so that they can be injected more readily with a gelatin mass stained with carmine. I have practically come to the same conclusion as Einhorn, who has worked along similar lines; namely, that:

> The arteries in the submucosa, in the pyloric region of the lower lesser curvature of the stomach, are practically terminal vessels and are relatively sparsely distributed, giving a limited blood supply to this area. They are tortuous, anastomose infrequently, and are subject to powerful and repeated forcible contractions by numerous interlacing, intricate and frequently contracting muscle bundles. These constrictions tend to interfere with the circulation and, moreover, the terminal vessels are subject to the same tendency to circulatory interference by reason of easy blocking as are the terminal vessels in the brain or the kidney, and are especially liable to harbor the foci of anemia.

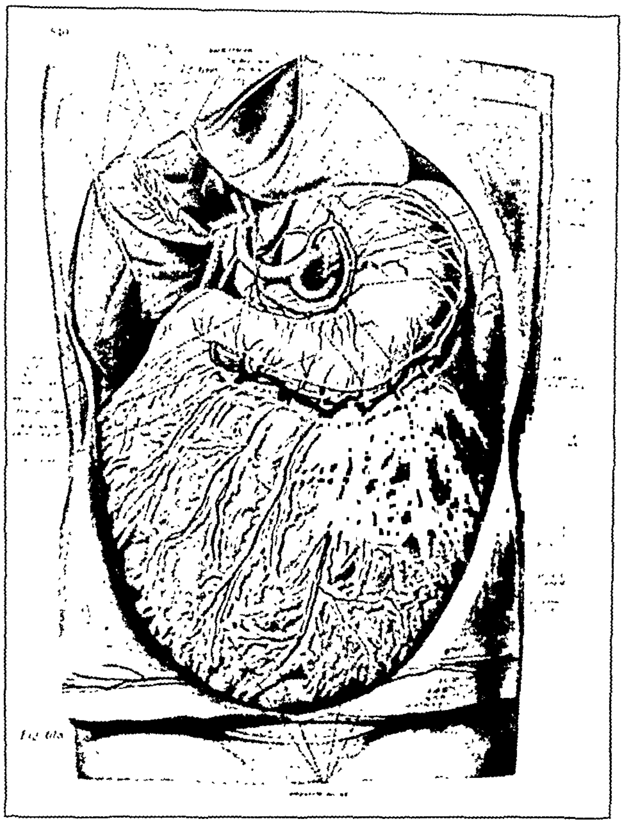

Fig. 1.—Note the anemic area around the pylorus. The arteries in this region are end vessels with practically no anastomosis.

As soon as perforation occurs, secretions of the stomach or duodenum, as well as the food content, exude. These acrid discharges, no doubt, have a tendency to seal any small blood vessels in the wall of the ulcer. Another factor militating against hemorrhage is the adhesion of the walls of the perforation to the surrounding tissues. Again, a protective lymph which surrounds the perforation helps to protect not only bleeding but also the escape of the contents of the viscera.

Bleeding ulcers rarely perforate. Ulcers that give rise to hemorrhage are more apt to occur in the pliable elastic tissue of the stomach and duodenum than in the denser area around the pylorus. Ulcers that bleed are not always readily located. No definite place can be assigned to this type of ulcer. One naturally always looks first in the ulcer-bearing areas. At times, however, it becomes necessary to explore the mucous membrane of the stomach thoroughly before finding the point of bleeding. Again, it is frequently impossible to find the source of hemorrhage, because the entire mucous membrane of the stomach seems to be in a state of congestion, blood oozing from every surface where it is touched. However, if the source of hemorrhage cannot be found at all, one must visualize the possibility of dilated esophageal veins as its cause. In the presence of cirrhosis of the liver, for instance, one can readily make a diagnosis of dilated esophageal veins. The appendix has also been held responsible for hematemesis; Deaver has mentioned cases cured after an appendectomy.

There is some difference of opinion concerning the question whether surgeons should or should not operate while the patient is bleeding. They know which course to pursue if bleeding is present from any other source. The same holds true in patients bleeding from gastric or duodenal ulcers. The patient ought to be operated on and the source of hemorrhage located. If an ulcer is found, excision should be practiced. True, ulcers that bleed are more difficult to find than those which perforate, for the reasons stated before: first, because they do not always occur in the classic situation of ulcers and, second, the latter are usually found in the more elastic areas of the stomach and duodenum. An illustration is afforded by a patient, a woman, whom I saw in consultation in a neighboring city. She had hematemesis and bloody stools, with outward signs of severe loss of blood. I advised a blood transfusion if the bleeding continued and then operation for the source of bleeding. This advice was not followed; the patient bled to death. Tragic deaths occur in those who have secret bleeding from gastric or duodenal ulcers without any external signs of its taking place. This occurred in two young men during the night; they were to have been operated on the next morning. The nurse on her rounds during the night found them dead.

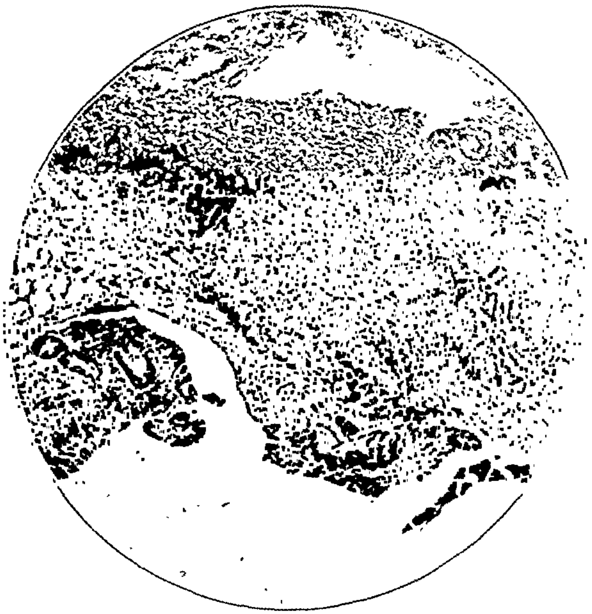

Fig. 2 (Davidsohn).—Only a few islands of gastric mucosa are seen. The remaining part shows a deep ulcer reaching down into the muscularis. The surface of the ulcer is covered with a fibrinous exudate. The muscularis is densely infiltrated with many leukocytes. The blood vessels are compressed. These ulcers rarely bleed.

It is my opinion that to defer operation for bleeding ulcer in the hope that the ulcer may not bleed again is an error of judgment.

REPORT OF CASES

A man, aged 30, admitted to Mount Sinai Hospital, Nov. 26, 1928, in the private medical service of Dr. A. I. Rubenstone, had been well until a year and a half before. Two days before admission he had passed blood by the bowel and on the day of admission he passed blood. He was anemic and undernourished and he complained of palpitation. The abdomen was tender in the epigastric region. Under treatment for ulcer, and by means of transfusion, the bleeding stopped to a marked degree. Small amounts of blood were always passed by the bowel. The patient was operated on two weeks after admission. No distinct ulcer could be felt, but on the serous surface there was evident stippling of the serous coat. This portion was excised and a tiny ulcer was disclosed. A pyloroplasty completed the operation. A pathologic report confirmed the ulcer macroscopically and microscopically (fig. 3). The patient has had no recurrence since operation.

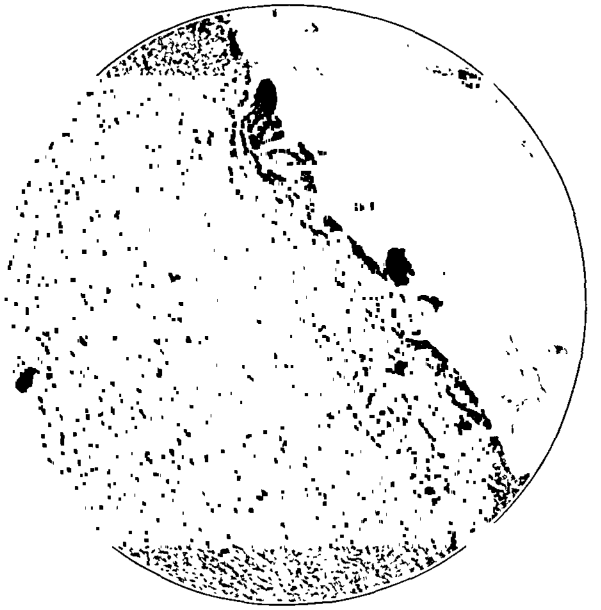

Fig. 3 (Davidsohn).—Here is found a pronounced inflammatory reaction at the bottom of the [illegible] ınd cell infiltration with occasional eosinophil and [illegible] ıd a young granulation tissue with fibroblasts and [illegible] are the bleeding ulcers.

Recurrent hemorrhagic ulcers after their excision are rare. A case of this character, however, first came under my notice three years ago:

A man, aged 21, was admitted to the Jewish Hospital in the private service of Dr. E. A. Heller, May 1, 1927. The symptoms began four years previously. In February, 1923, there was severe vomiting of food, followed by hematemesis. Blood was noticed in the stools. He did not complain of pain. He vomited at least twice a day. In November, 1923, he had a similar attack, losing so much blood as to incapacitate him for two months. The following April he had a third attack, which was not as severe as the previous one. He had four bloody stools. In April, 1926, he had a fourth attack of hematemesis. Since then, infrequent attacks of a dragging sensation over the upper part of the abdomen caused occasional attacks of nausea. He gained no weight in three years. He had the typical appearance and physiognomy of the ulcer patient. Fluoroscopic examination showed that the stomach filled normally. It was the shape of a fish-hook. There were no filling defects in the stomach. The duodenal cap showed a filling defect along its upper border, evidently the site of an ulcer. Operation was performed, May 7, 1927. A well defined ulcer was found; a stellate scar on the serous coat near the pylorus was outlined. The ulcer was removed and a posterior gastro-enterostomy performed. The pathologic report was benign ulcer.

The patient was readmitted, July 4, 1928, with a complaint of hemorrhage from the bowel. For the past two weeks the patient had seen bloody stools. July 5, he had a profuse hemorrhage which made him extremely weak and dyspneic. A blood transfusion was performed, and the next morning the old site of the ulcer was found. Attached to the mucous membrane was a piece of linen thread from the previous operation, which seemed to be the cause of the hemorrhage. This was excised with the ulceration it had caused.

The patient was readmitted, Feb. 26, 1930, with a profuse bleeding from the bowel. Transfusion was performed on admission. He was operated on, the next morning, and just beyond the old scar of operation there was a series of soft pliable ulcers. A large portion of the anterior wall of the duodenum was excised. The mucous membrane was pitted and furred. Beyond this area the mucous membrane was normal. This was rather a remarkable case, because within three years the patient had had three distinct ulcers, the last seemingly a group of ulcers lining the mucous membrane of the duodenum.

COMMENT

Perforative ulcers occur more frequently than bleeding ulcers. This fact is also difficult of explanation. In one year I operated on twenty-four perforated ulcers; during this time not one case of bleeding ulcer was observed. The exact ratio is not known, but I should judge that about one in twenty-five bleeds.

It is interesting to note the gross pathologic difference in vivo between the chronic ulcer, the perforating ulcer and the bleeding ulcer. No one can mistake the hard, indurated, punched-out ulcer for any other type. Here the edges of the ulcer are firm; the base of the ulcer is devoid of mucous membrane, being displaced by firm connective tissue. The base of the ulcer is of varying depth, depending on its chronicity. These ulcers do not bleed because the blood vessels have been partially obliterated by the hard connective tissue. They may perforate, depending again on the thickness of the base of the ulcer. The bleeding ulcer is usually an acute condition: hence the area affected is much smaller in extent. The edges of these ulcers are soft, with rounded borders; the surrounding mucous membrane is

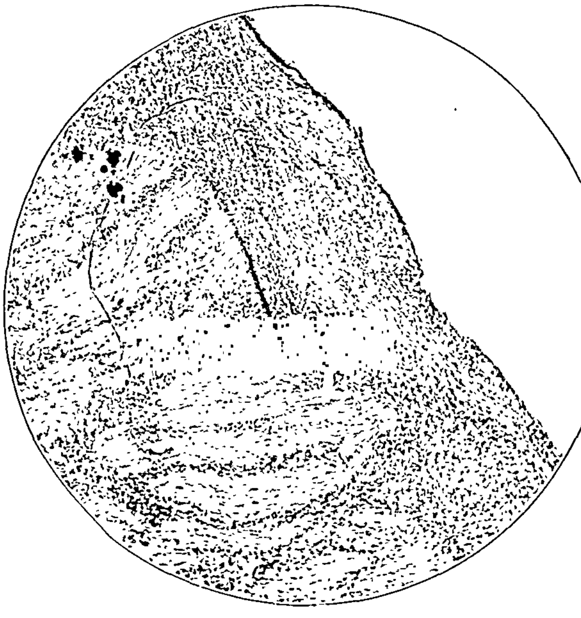

Fig. 4 (Davidsohn).—The section shows a mild inflammatory reaction consisting of a moderate infiltration with round cells and leukocytes. The edges are covered with a thin layer of fibrinous exudate. Another type of bleeding ulcer.

congested and it often becomes difficult to locate the source of bleeding unless one opens the suspected viscus. Even then, one may not find the source of the bleeding. The perforated ulcer usually follows the description of the chronic ulcer with the added picture of perforation. There is found a solution of continuity in the center of an indurated wall of the stomach or duodenum. The same is true of perforations without previous gastric symptoms. Another type of perforation is found when the wall surrounding the ulcer is perfectly flaccid with little or no inflammatory reaction. This is a rare condition of which I have seen one case.

The histologic picture of the ulcers described can be verified when placed under the microscope. For instance, in the chronic type (fig. 2), the base of the ulcer shows a few small blood vessels. They have been pressed on by the proliferation of fibrous tissue. As a consequence, these ulcers do not bleed as readily as the acute or subacute type. In these there is very little inflammatory reaction, with almost an entire absence of connective tissue elements. The blood vessels, therefore, have not been compressed because of the absence of scar tissue, such as is found in the chronic ulcer. Also in the acute and subacute forms the capillaries are large, which naturally predisposes to hemorrhage (figs. 3 and 4).

CONCLUSIONS

The fact that bleeding ulcers rarely perforate and perforated ulcers rarely bleed may be explained by anatomic physiologic and pathologic observations.

Anatomically, there is a bloodless area around the pylorus responsible for some of our deductions; physiologically, the exuding juices prevent hemorrhage, while pathologically the age of the ulcer determines whether it is going to bleed or not.

1738 Pine Street.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. STRAUSS, BLOCH, FRIEDMAN, MEYER AND PARKER AND DR. BEHREND

Dr. Roy D. McClure, Detroit: The title of the paper by Dr. Strauss and his collaborators first suggested to me Dr. Lane's colectomy in the prevention of old age; that is, it seemed like a tremendously radical procedure. I would like to know, perhaps after fifteen or twenty years, the end-results of these cases. Better conclusions can be drawn from the series presented by Dr. Strauss if they can be followed and reported again in ten years. Our experience in duodenal ulcer is that, largely, it is a medical disease with only an indirect surgical approach, such as the removing of tonsils, infected teeth, abscesses, perhaps appendixes and even gallbladders in which infection is present. Perhaps the authors mentioned the percentage of duodenal ulcer patients which they have in the hospital that are operated on. If not it would interest the section to know. When we do operate on a patient with a duodenal ulcer, we do either a pyloroplasty with destruction of the muscles of the pylorus, or a posterior gastro-enterostomy. In only a limited number of cases are we doing a more radical procedure, and our results have been extremely good. We have a number of cases in which the pylorus is involved by the ulcer. In the experience which I relate, I give our reason for a two-stage operation instead of a single-stage operation if a resection has to be done. I recall two cases in which there was involvement of the duodenum and the pylorus, with an extremely wide inflammatory reaction around the ulcer, and it was difficult at the operation to tell whether cancer had already developed in this area. Two-stage operations were decided on and high posterior gastro-enterostomies performed. Two weeks later we went in to resect the pylorus and first part of the duodenum, and much to our amazement the tumor mass had entirely disappeared. Both of these patients have been followed, and they have had no further trouble. For that reason, I should feel that all these cases of operative ulcer could perhaps first have the advantage of a high posterior gastro-enterostomy, and then, if in a month or two months or six months the patient is not well, a subtotal resection of the stomach is much easier to perform, and I believe the risk and the end-results would be even better than those of Dr. Strauss and his associates which are good, as shown by their statistics. I feel that the doctrine of such radical surgery practiced by average surgeons is rather a dangerous doctrine. If a subtotal gastrectomy is indicated, perhaps it should be done by surgical teams here and there who gain skill through the large number of these operations they have done.

Dr. Richard Lewisohn, New York: Partial gastrectomy for duodenal ulcer yields much better end-results than more conservative procedures, gastro-enterostomy, local excision and pyloroplasty. The main object of any surgical procedure should be a permanent cure at the time of the primary operation. It is well known that the so-called conservative methods fail to cure the patients in a large percentage of instances. In my material, a careful follow-up of gastro-enterostomies showed that less than 50 per cent of the patients were completely cured, and that 34 per cent suffered from gastrojejunal ulcer. In 16 per cent, this diagnosis was proved by reoperation. The other 18 per cent (proved by x-rays) refused reoperation or went to other hospitals. It is interesting to find that my observation in 1925, of the high incidence of gastrojejunal ulcers has been confirmed, not only by Dr. Strauss and his associates but also by similar statistics published by a number of other clinics. Two main arguments have been advanced against subtotal gastrectomy in gastroduodenal ulcers: (1) that the mortality is apt to be excessive, and (2) that this method represents an unnecessarily mutilating procedure. The retrocolic Billroth II method (either in the form of the Hofmeister anastomosis or in very high gastric resections with the aid of a button) has given satisfactory results in my hands. The mortality in primary operations for chronic gastroduodenal ulcers over a period of eight years was 2.27 per cent, certainly not a prohibitive mortality. Acute bleeding ulcers, operated on either during or immediately after a profuse hemorrhage, are not included in this series. As to the second point, I consider gastro-enterostomy which fails to cure one out of two patients, and which is followed by gastrojejunal ulcers in about one out of three patients, a much more mutilating procedure than subtotal gastrectomy. I have seen patients who had to undergo six and more surgical operations until gastric resection cured them. What an economic waste. The majority of American surgeons favor gastro-enterostomy, whereas the surgeons in Germany and Austria favor gastric resections. I understand that Starlinger has recently collected about 25,000 case reports of partial gastrectomy for ulcer from eighty-five clinics in Germany and Austria, a most impressive figure. The number of recurrences in this series were less than 1 per cent.

Dr. Leon Bloch, Chicago: In an experience with more than a thousand cases of duodenal ulcers I have become somewhat skeptical about the results of medical treatment. The 80 per cent of medical cures in former reports have dwindled to less than 50 in more recent ones. The frequent finding at autopsies of ulcer scars in the duodenum often without symptoms during the life of the individual prove that ulcers heal and heal spontaneously. However, remissions of five or more years do not mean that cure has been effected because the occurrence of hemorrhage and perforation in apparently cured cases are tragic evidences of failure. New ulcers may continue to form in one with ulcer tendency. This apparent failure of medical measures, however, does not mean that operation is recommended for every case. Perforation, repeated or severe hemorrhage and organic stricture are the definite indications for surgery. What, then, should be done? I tell my patients that there is no time limit to the treatment and that they may have to restrict their diet for one or more years or even indefinitely if they wish to avoid an operation. Hemorrhage with or without pain is a very frequent symptom of gastrojejunal ulcer following gastro-enterostomy for duodenal ulcer. Hurst in his recent book on ulcer states that many patients who did not bleed before the operation bleed after gastro-enterostomy. This is in accord with our views. Pain is the most common symptom; it is often more intense and is less amenable to treatment than the original ulcer. Gastrojejunal ulcer is rare after resection and the dangers of the operation are much less than for the secondary operation for jejunal ulcer after gastro-enterostomy. In fact, the mortality rate of resection in my private patients operated on by Dr. Strauss is much smaller than reported by him. Undoubtedly the better physical condition of these patients at the time of operation accounts for this. Recovery occurs after a period of readjustment of from three to six months. During this time the jejunum dilates sufficiently to take care of the increased burden thrown on it and the patient learns to chew his food properly, thereby avoiding the troubles of an irritable colon. He then may eat what he wants and when he wants to and have no discomfort. Such results certainly speak for resection as against gastro-enterostomy.

Dr. Bernard Portis, Chicago: I wish to report some of our experimental work on the effects of gastrectomy and gastro-enterostomy on gastric secretion and upper intestinal flora. This work was started about nine years ago, in association with Dr. Alfred Strauss at the Nelson Morris Institute of the Michael Reese Hospital. I found that dogs subjected to gastro-enterostomy, compared to dogs having a gastric resection, did not have a materially altered gastric secretion because of the gastro-enterostomy, whereas dogs that had a partial gastrectomy had a resultant anacidity or absence of free acid after this operation. When the emptying time was tested under a fluoroscope, the dogs that had a gastro-enterostomy emptied in about the same time as normally, whereas the dogs that had a gastric resection emptied in from a third to a half of the previous normal. There are two important facts to be considered in the question of the outcome of the two operations for the cure of duodenal ulcer. The acid is practically absent or completely neutralized in the remaining stomach, and the emptying time is quicker after partial gastrectomy, whereas the contrary is the case after gastro-enterostomy. Another important feature that I studied was the effect of these two operations on the upper intestinal flora. I am not going into the details, because it was published a few years ago in one of the journals. However, the conclusions are as follows: The upper intestinal flora, especially in the jejunum, tends to become fecal in type in partial gastrectomy, whereas the upper intestinal flora in gastro-enterostomy remains practically the same. What results will ultimately occur from this change in the upper intestinal flora will demand future observation. However, it is not to be overlooked that perhaps some time, in ten or twenty years, serious results, more especially serious anemias, may occur in patients who have had gastric resection, although the immediate clinical results are much better after this type of surgery. Another feature which we observed in patients who have had a gastro-enterostomy is that the ulcer should not be considered cured just as soon as the anastomosis is made. Patients require ulcer management for a considerable period in order to prevent the recurrence of the ulcer. Also those individuals who have had hemorrhages from duodenal ulcers and have had gastro-enterostomies frequently have subsequent hemorrhages.

Dr. William J. Cassidy, Detroit: This ulcer question has been the battle-ground of the surgeon and the medical man for a great many years. Gastro-enterostomy, when it first came out, was done for every condition in the abdomen which had any signs or symptoms or even suggestible symptoms referable to the stomach. Since the advent of the roentgen ray, this has put gastric and duodenal diagnosis on a more accurate basis, so that fully 95 per cent of the gastroduodenal ulcers and gastric ulcers should be diagnosed by a fairly good roentgenologist or by a good roentgenologic surgeon. This axiomatic fact must be borne in mind: Any operation that leaves stomach tissue leaves a potential area for ulcer, irrespective of who does it. Any surgical procedure that carries a high incidence of mortality for the average surgeon is not the best type of operation to advocate at large. We decry medical management. The medical man isn't a bad fellow if he is given half a chance. Let him treat the patient first. The trouble with surgeons is that the patients with acute ulcer too often come first to the surgeon and the patients with chronic ulcer too often come first to the medical man. European surgery cannot be applied to American surgery. The average American will not listen to rule or reason. If a law is made, the patient will try to break it. That is what is wrong with the treatment of ulcer in the United States today. These patients will not stand regulation. In about 200 perforating ulcers that I have seen, about 35 per cent bled previous to perforation. They did not bleed at the time of perforation. Any ulcer, especially if it is localized at the lesser curvature of the stomach, along the larger blood vessel, if it erodes into a vessel, is going to bleed. The acute perforating ulcers rarely bleed, they go through so quickly. I have seen them go through in twenty-four hours. They are punched out, there is no inflammatory process; it is too rapid; and they are usually streptococcic.

Dr. Clark D. Brooks, Detroit: I think that there is less and less need of operating on ulcers on account of better medical management. A great many patients, I believe, are operated on with different types of operation for duodenal ulcer that do not need operation at all and would get well if they had good medical management by a competent medical associate. I think gastro-enterostomy is often condemned because, first of all, it is done when it is not necessary. I believe that a properly made gastro-enterostomy by a properly qualified surgical team will show good results in more than 90 per cent of patients. My own belief is that the ideal treatment for chronic duodenal ulcer which has not responded to good medical treatment in most cases is to destroy the ulcer with the actual cautery at the time of the operation and to perform a large no-clamp method of gastro-enterostomy. Regarding the bleeding ulcer, I do not believe that the patient who comes into the hospital in an ambulance, with hemorrhages, should have an operation until he has had a blood transfusion, intravenous dextrose and a fair trial of starvation and good medical management. If operation is performed in these cases of the acute bleeding type, many of the patients will die on the operating table in spite of emergency blood transfusions, because there may be an esophageal varix as the cause of the bleeding and the operator cannot tell whether it is an ulcer case or not unless there was a previous roentgen examination made. The desired end-result of any procedure is to relieve the patient of his symptoms as safely as possible and to allow him to be self-supporting. Every case of duodenal ulcer should continue to be under good medical supervision, whether the patient has had any surgical treatment or the type of surgery advised.

Dr. Frank H. Lahey, Boston: I feel sure that the outcome of these discussions leaves one with the feeling that the procedure is largely affected by whether one is a physician, a surgeon or, most important of all, a patient.

Dr. A. A. Strauss, Chicago: I doubt whether much will happen to a successful subtotal resection at the end of ten years—I mean one that has been successful for ten years—and I am afraid some of us in twenty-five years won't be here to know what happens. But it cannot be denied that our results correspond with the results of the various clinics in other countries, and I believe a human being in Austria is the same as one in New York. As to the anemias, we have had only two cases of anemia. One was in a case presenting diarrhea before operation and diarrhea after operation. This diarrhea has ceased and the anemia has disappeared. One patient still has anemia. That was in the case of a bleeding ulcer, and the patient has never recovered from anemia. These are the only patients that I know of in our series of 221 resected cases that had anemia. As to the point that Dr. Brooks made, we believe that 95 per cent of all ulcers stop bleeding and the blood transfusion helps to stop the hemorrhage, and then we operate only if there is a history of a fatal or near-fatal previous hemorrhage. We believe that a patient who comes into the hospital with a second hemorrhage should be operated on within two or three weeks after the hemorrhage has ceased, with several blood transfusions, and then a subtotal resection done. About 20 per cent of the patients who come to us—in a group we get a large number of patients who have been in various clinics—are operated on. We believe that the patients on whom we operate, usually for clover-leaf deformities of the duodenum, are suffering from an anatomic deformity, in other words a partial anatomic obstruction, which no medical treatment can cure; and those are the majority of the cases in which we do a subtotal resection. We know that 65 per cent or more of the patients that are operated on have a duodenal ulcer penetrating the posterior wall, and those are the cases that we believe are distinctly surgical and not medical.

Dr. Moses Behrend, Philadelphia: I am glad Dr. Strauss and his co-workers mentioned the fact concerning the clamps. I still use the clamps, but the more I use them the less I like to use them. I believe that a great deal of harm is done by the use of clamps, especially the Payr clamp. Entirely too much pressure is exerted on the delicate structures of the stomach and duodenum. Concerning acute hemorrhage, I thought some exception would be taken to that statement; but the more I see of these cases of bleeding, the more I believe that they should be treated the same as any other case in which there is bleeding. With the proper preoperative treatment, such as blood transfusions, dextrose and all the things that have been mentioned here, there is no reason why operation cannot be performed ten or twelve hours after the hemorrhage. I have seen no harm result from this, but I have seen a lot of good, and I have lost no patients as a result of operative intervention in those cases. It is true, as Dr. Lewisohn has stated, that these ulcers usually occur on the caudal side of the pylorus, on the posterior wall of the duodenum or on the posterior wall of the stomach, and one should never hesitate, if there is no exterior sign of ulcer, such as stippling of the serous coat, to do a gastrotomy or a duodenotomy and find out where the bleeding point is. That is the proper procedure. I have never experienced a hemorrhage occurring two or three months before perforation. I have never had a case of that character. In all my cases there was either bleeding or perforation. As for subtotal resection versus gastro-enterostomy, I still feel that one ought to choose the operation for the individual case and that it doesn't seem right to make a dogmatic statement concerning this fact, that gastrectomy should be done in almost every case in which a duodenal ulcer is found. I believe that it depends solely on the judgment of the surgeon, the condition of the patient and the patient himself.

SUBCUTANEOUS NODULES IN RHEUMATOID (CHRONIC INFECTIOUS) ARTHRITIS *

M. H. DAWSON, M.D.
AND
R. H. BOOTS, M.D.
NEW YORK

The occurrence of subcutaneous nodules in patients suffering from rheumatic fever has long been recognized and has been the subject of intensive investigation by many workers. Carey Coombs [1] has recently stated that of all manifestations of orthodox rheumatic infection—carditis, polyarthritis, subcutaneous nodules and chorea—the subcutaneous nodule is the most "rheumatic" of all. Swift [2] and other investigators have from time to time expressed similar views. Considerably less attention, however, has been paid to the subcutaneous nodules that occur in patients afflicted with rheumatoid arthritis [3] notwithstanding the fact that in this disease such a manifestation is an even more striking phenomenon.

One of the oldest and, at the same time, one of the most complete descriptions of these nodules is that given by C. O. Hawthorne [4] in a monograph in which he describes the occurrence of subcutaneous nodules in a series of six patients and expresses the opinion that rheumatic fever and rheumatoid arthritis are different manifestations of the same fundamental process. Histologic descriptions, however, are entirely lacking and there remains an element of doubt as to whether some of his cases may not have been cases of gout. Garrod,[5] in his classic description of rheumatoid arthritis in 1910, refers to the occurrence of subcutaneous nodules in this disease. On clinical grounds Garrod differentiates these nodules from those found in rheumatic fever, but no histologic studies are presented. Wick [6] of Vienna in 1910 described similar nodules and called attention to the relationship between them and those found in rheumatic fever. In 1926, Coates and Coombs [7] described the histologic structure of subcutaneous nodules in three cases—one of rheumatic fever, one of rheumatoid arthritis and one of Still's disease. They conclude that the nodules in the three diseases are very closely related if not identical structures. In 1928 Freund [8] published a full description of the nodules and thoroughly discussed the relationship between rheumatic fever and rheumatoid arthritis.

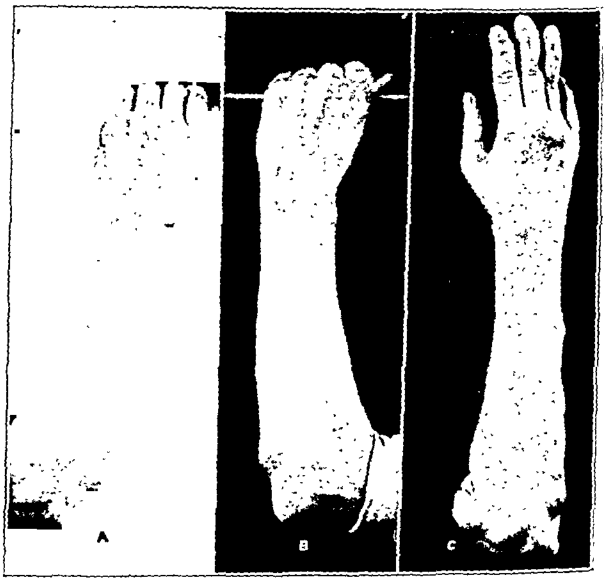

Fig. 1.—Subcutaneous nodules in rheumatoid arthritis: *A*, *B*, symmetrical distribution from 4 to 5 cm. distal to olecranon. *C*, large nodules on dorsal surface of forearm; note typical "rheumatoid" deformity of hand.

Since the establishment of the arthritic clinic in this hospital a year ago, subcutaneous nodules have been observed in forty patients. Approximately 200 patients with true rheumatoid arthritis have been seen in the clinic during this period, so that the incidence of patients with nodules is relatively high—approximately 20 per cent. However, since attention has been focused on this particular phenomenon, the incidence among patients at large is possibly somewhat less.

[3] The Arthritic Clinic of the *Presbyterian Hospital* has adopted the terminology and classification of rheumatic diseases advocated by the British Ministry of Health. Chronic joint changes are divided into the following categories: (1) rheumatoid arthritis (*American* "*chronic infectious*" and "atrophic"); (2) osteo-arthritis (American "hypertrophic" and "degenerative"); (3) gout; (4) unclassified. This classification has been recommended by the International *League for the Control of Rheumatism* and therefore possesses the advantage of widespread use.

The nodules have been observed only in cases of typical rheumatoid arthritis and in one case of Still's disease. They have never been recognized in cases of osteo- (hypertrophic, degenerative) arthritis. Three of the patients in whom the nodules occurred presented a history of a previous attack of rheumatic fever. Four patients showed definite evidence of rheumatic heart involvement. In one patient the development of arthritis and the appearance of nodules appeared to bear a definite relationship to a previous attack of scarlet fever.

DETAILED OBSERVATIONS OF NODULES

Size.—The nodules vary in size from small, scarcely palpable, seedlike bodies to large excrescences the size of olives.

Situation.—The site at which they are most commonly observed is on the dorsal surface of the forearm at a point about 4 cm. distal to the olecranon. They are also seen over the olecranon itself, in the wall of the olecranon bursa, over the dorsum of the forearm and hands, over the knees, the sacrum and the scalp.

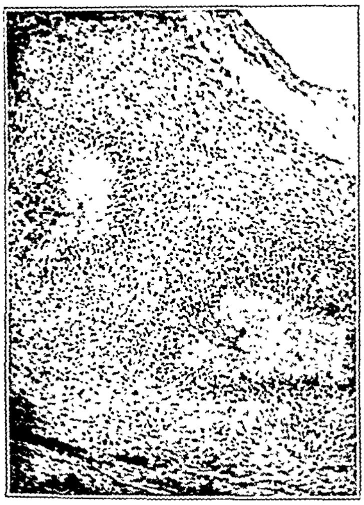

Fig. 2.—Appearance of a subcutaneous nodule in rheumatoid arthritis. (Hemotoxylin and eosin stain, low power.) Areas of central necrosis surrounded by zones of radially disposed histiocytic cells.

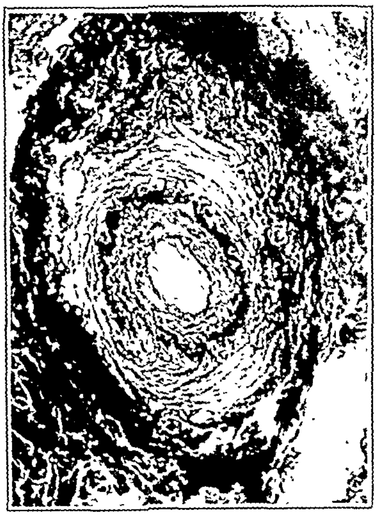

Fig. 3.—Vascular lesions of a subcutaneous nodule in rheumatoid arthritis. (Elastica stain, high power.) Subendothelial hyperplasia, splitting of elastica and formation of a new internal elastic membrane.

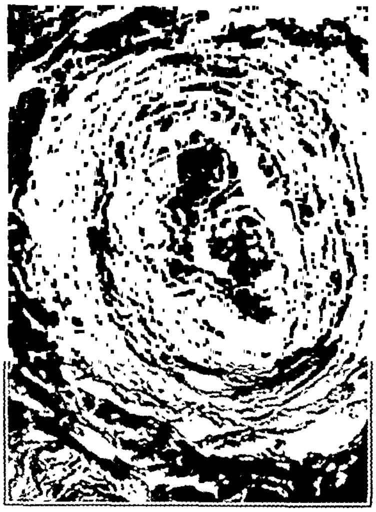

Fig. 4.—Vascular lesions of a subcutaneous nodule in rheumatoid arthritis. (Elastica stain, high power.) Arteritis verrucosa; polypoid projection from arterial wall into lumen of vessel.

Consistency and Attachment.—The nodules are usually moderately firm in consistency and discrete in their outline. They always occur in the subcutaneous tissue; they are not attached to either the skin or the underlying periosteum but frequently show a relationship to tendon sheaths and the walls of bursae.

Evolution and Duration.—As a rule these nodules develop slowly and persist over long periods of time—frequently for many years. The smaller ones, however, run a more acute course and may appear and disappear within a few months, occasionally within a few weeks.

Type of Case and Prognosis.—These structures are, for the most part, observed in severe cases and generally indicate an unfavorable prognosis.

Pain.—The nodules are never painful and only in rare instances do they cause the patient any inconvenience.

Histologic and Bacteriologic Examination.—Nodules have been excised from fourteen patients and subjected to careful histologic and bacteriologic examination. All the material examined shows a striking, uniform and characteristic picture. Histologically the essential features may be briefly outlined as follows:[9]

1. An area of central necrosis, apparently due in its earliest stages to a gelatinous swelling and disintegration of collagen bundles. Depending on the age of the nodule and the severity of the process there is a variable amount of fibrin deposition and inflammatory cell infiltration. As a rule the necrosis is much more extensive and the process much less acute than that seen in rheumatic fever nodules, but all intermediate stages may be seen.

2. A surrounding zone of peculiar and characteristically arranged large mononuclear cells. These cells are, for the most part, disposed in radial fashion and are largely responsible for the characteristic appearance of the whole lesion.

3. An enclosing zone of dense and relatively avascular fibrous tissue. The blood vessels in the area of the nodules themselves only rarely show significant changes, but the arterioles and capillaries in the surrounding tissue are the site of characteristic lesions. These may be summarized as follows:

(*a*) Subendothelial deposition of fibrin, hyperplasia of subendothelial cells, narrowing and even occlusion of the lumen, and, in some instances, canalization of the hyperplastic intima.

(*b*) Splitting of the elastica, and occasionally the formation of a new internal elastic coat; polypoid projections into the lumen.

(*c*) Perivascular cell infiltration by large mononuclear and small round cells.

The bacteriologic investigations have been entirely negative.

With the exception of those peculiar to rheumatic fever, similar nodules have not been observed in any other disease. There is no relationship between this manifestation of rheumatoid disease and the cutaneous and subcutaneous lesions encountered in syphilis, gout or tuberculosis.

---

[9] We are indebted to Dr. A. M. Pappenheimer of the Department of Pathology, Columbia University College of Physicians and Surgeons, for his assistance in the study of the nodules. More complete descriptions will shortly be published with his collaboration.

This study therefore sustains the following conclusions:

1. The subcutaneous nodule occuring in rheumatoid arthritis is a classic lesion of this disease.
2. The histologic appearance of these nodules is uniform and highly characteristic.
3. There is a striking histologic resemblance between the subcutaneous nodules occurring in rheumatic fever and those observed in rheumatoid arthritis.

COMMENT

The relationship between rheumatic fever and rheumatoid arthritis has long been a matter of speculation among clinical observers. Since the time of Heberden (1782) and Haygarth (1805), who were first responsible for the distinction between "acute" and "chronic" rheumatism, the opinion of clinicians has been divided into two schools: those who maintain that the two conditions are entirely separate diseases, and those who consider that they are different manifestations of the same fundamental pathologic process. Among the proponents of the former concept may be mentioned Adams (1857); A. B. Garrod (1859), who first employed the term "rheumatoid arthritis"; Bristow (1884); Fagge (1886); Osler (1892), and Sir A. E. Garrod (1908). Supporters of the contrary theory were Jonathan Hutchison (1881), Charcot (1881), Sir Dyce Duckworth (1884) and Hawthorne (1900). More recently the conception that the two conditions are different manifestations of the same process has received support from Kahlmeter[10] in Sweden and Coates[11] in England.

It is not our purpose in this communication to support either of the two theories or to survey the clinical evidence for or against either hypothesis. The striking histologic resemblance of the subcutaneous nodules in the two conditions suggests the possibility that these two clinical entities may be different manifestations of the same fundamental disease process. However, it will not be possible to express a final opinion as to the relationship of rheumatic fever and rheumatoid arthritis until the etiology of both conditions is definitely established.

Unusual Mental Honesty.—The scientific mind in its purest form . . . is one that functions invariably in the light of truth, and one that is entirely unbiased by ulterior motives. It is not something that is possessed by men of science alone, nor are they always in possession of it; it is quite as much a characteristic of artists, or of men in other professions. It reveals itself, to a considerable degree, in that unusual mental honesty which the scientist displays in doing his work. . . . A mental bias may enter into his zeal for facts as much as it may disrupt the clear reasoning of a layman; and yet both may have the "scientific mind" when they surmount the inferences and generalizations that are common to the ordinary mind. Since the works of art and the theories of science are the achievements of their creators, they necessarily show both the strength and the limitations of the minds that conceive them. . . . If science and art can bring man to a fuller comprehension of his relation to the universe and his place in nature, his religion, philosophy and esthetics will be profoundly affected: but science has not yet advanced far enough to dictate the terms of understanding or appreciation of these branches of thought, even though we are constantly being called upon from every quarter of the scientific world to listen to the new discoveries. —Saidla, L. E., and Gibbs, W. W.: Science and the Scientific Mind, New York, McGraw-Hill Book Company, Inc., 1930.

GROWTH OF BONE AND DEVELOPMENT OF RICKETS

RELATIVE SIGNIFICANCE OF CERTAIN ASSOCIATED FACTORS *

EDWARD CLAY MITCHELL, M.D.
AND
MARTHA V. NELSON, M.S.
MEMPHIS, TENN.

This work was undertaken not as a study of rickets but rather as a series of observations of the bone growth of normal, well infants, between 1 month and 1 year of age. The material for the study included fifty infants from private practice, ten infants from an institution and ten from a social center.

Standardized physical examinations and roentgenograms of the wrists were made at monthly intervals. Whenever possible, blood calcium and phosphorus determinations were made at the same time. A modification of Clark and Collip's[1] method was used for the blood calcium, and the Fiske-Subbarow[2] method for the phosphorus. The physical examinations were checked by three people with the same criteria in mind. The roentgenograms were taken by one technician using a three-eighths second exposure, at a distance of 35 inches, 50 peak kilovolts, 50 milliamperes, and 3-inch spark gap. The roentgenographic observations were interpreted by Dr. Sherwood Moore of the Barnes Hospital, Washington University School of Medicine, St. Louis.

The relative value of the different criteria for the diagnosis of rickets is still a subject of discussion. A few years ago Park[3] defined rickets as a disturbance of the metabolism in which the first detectable sign is a diminution of the phosphorus content of the blood. In a more recent paper Hess,[4] working with rats, advanced the idea that there is a local as well as a systemic factor which prevents proper calcification at the epiphyses. He obtained normal blood values without healing of ricketic lesions. The presence or absence of rickets, in the latter study, was determined by roentgenograms. As a result of the tendency toward greater dependence on the roentgenographic observations, it becomes of increasing importance that the normal and the ricketic changes in the growing bone be clearly defined.

In rickets the ulna is described by Hess[5] as presenting a "cupped" or "dished out" appearance with a spreading at the distal end of the bone. The epiphyseal margin of the radius presents an irregular contour, a spongy or rarefied appearance with the later development of an area of increased density.

The roentgenograms of the wrists of the infants of this study were examined with reference to each of these changes and the results tabulated. Of the seventy infants observed, eight, or 11.5 per cent, were classified by the roentgenologist as having normal bone development during the period they were under observation.

[5] Hess, A. F.: Rickets, Including Osteomalacia and Tetany, Philadelphia, Lea & Febiger, 1929.

Sixty-two, or 88.5 per cent, had roentgenograms which showed one or more irregularities, such as cupping and pointing of the ulna, an irregularity of the distal margin or an increased density of the lower metaphyses of the radius. The number and intensity of these changes varied widely. Eighty-four per cent of all these changes took place between 2 and 6 months of age.

Such observations at a glance indicate an inadequacy of the rickets-preventing factors and require a careful examination of the food and environment of the infants.

With the exception of the ten infants from the social center, all these children were receiving intelligent care. Milk was the chief item of diet and was fed in quantities equal to or greater than those commonly accepted as requirements at these ages. All of the children received orange juice. Four infants were breast fed until 6 months of age. None of the children received any proprietary foods or high carbohydrate diets. Vegetables, egg yolk and small quantities of cereal were added at age periods varying from 4 to 7 months. The study was made from December to May, inclusive, so the factor of sunshine was negligible. None of the infants received viosterol or ultraviolet ray exposures. The quantity of cod liver oil varied; hence a more detailed investigation of the influence of this article on the bone development was attempted.

TABLE 1.—*Instances of Irregularities of Bone Development of Infants from 3 to 12 Months of Age: Effect of Cod Liver Oil*

Daily	Number Examined	Number Showing Irregularities	Per Cent Showing Irregularities
No cod liver oil..........	38	29	77
Less than one teaspoonful..	42	29	69
One teaspoonful	70	55	79

This study included only seventy individuals, but every child was counted each time he was examined. Thus during the course of observation these 70 individuals became 150 infants, as they appeared 150 times for examination. This was made necessary by the fact that some of the infants belonged in the "no cod liver oil" group for the first one or two examinations and proceeded to the other groups as the cod liver oil was increased. Since irregularities in roentgenograms of bones rarely appeared before 2 months of age, all infants of this age and under have been omitted from this calculation (table 1). Of thirty-eight examinations of infants, 3 to 12 months of age receiving no cod liver oil, twenty-nine, or 77 per cent, showed some irregularity of bone development. Of forty-two receiving less than one teaspoonful daily, twenty-nine, or 69 per cent, showed irregularities, and of seventy receiving one teaspoonful of cod liver oil daily, fifty-five, or 79 per cent, presented one or more irregularities of bone development.

The presence of this amount of cod liver oil in the diet of these infants did not produce symmetrical bone development. The greatest percentage of irregularities occurred in the group receiving the most cod liver oil; i. e., one teaspoonful daily.

These figures may be summarized with reference to growth and some interesting relationships develop. As in the study of the effect of cod liver oil, the babies were counted as many times as they appeared for examination and were divided into three groups. Those whose gain in weight averaged 5 ounces (140 Gm.) a week for that month were designated as "average." Those who gained less were classified as "slow" and those gaining more were designated as "rapid" (table 2).

Of forty-four infants in the slowly growing group, thirteen, or 30 per cent, showed irregularities of bone development. Of sixty-seven in the average growing group, forty, or 60 per cent, and of seventy-seven in the rapidly gaining group, sixty-eight, or 89 per cent, showed some of the changes frequently called ricketic.

TABLE 2.—*Instances of Irregularities of Bone Development of Infants: Effect of Rate of Growth*

Growth	Number Examined	Number Showing Irregularities	Per Cent Showing Irregularities
1 to 12 months of age:			
Slow	44	13	30
Average	67	40	60
Rapid	77	68	89
3 to 12 months of age:			
Slow	27	14	52
Average	58	38	66
Rapid	65	61	94

Omitting the thirty-eight roentgenograms of infants 2 months of age and under, fourteen, or 52 per cent, of twenty-seven infants in the slowly growing group showed irregularities of bone development. Of fifty-eight in the average group, thirty-eight, or 66 per cent, showed irregularities. Sixty-one, or 94 per cent, of the sixty-five infants in the rapidly gaining group showed some irregularities of bone growth.

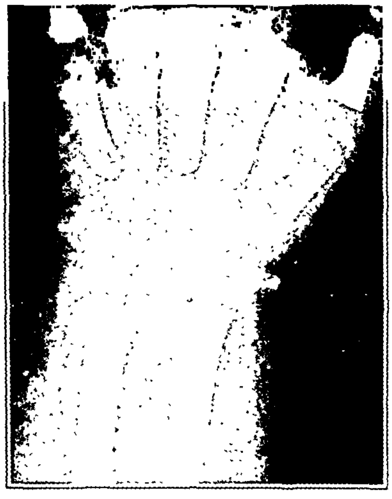

Fig. 1.—Bones with smooth and regular contours; classified as normal by roentgenologist.

Much has been said of the rickets produced by rapid growth, but should it be necessary to stunt infants in order to prevent the development of rickets? Should not an infant be allowed to gain as he will provided his food intake is properly balanced? It may be that one teaspoonful of cod liver oil is an inadequate amount for a rapidly growing infant, but we believe one should consider not only whether or not infants grow too rapidly or receive too little cod liver oil but also whether these minor bone changes in the early months of life are ricketic in nature.

TABLE 3.—*Appearance of the Physical Signs of Rickets in Seventy Infants from 1 Month to 1 Year of Age*

Characteristic	Instances	Per Cent
Beading	48	70
Flaring of ribs.....................	1	1.4
Slow closing of fontanel............	4	5.7
Thickened wrists	..	..
Square head	..	..
Pot bellies	..	..
Bowlegs	.	..

The prevalence of the physical changes ordinarily associated with rickets is shown in table 3.

In many hospitals and private clinics a diagnosis of rickets is recorded on the basis of a perceptible beading of the ribs. We doubt whether many but experts are capable of distinguishing between moderate ricketic beading and the normal angulation. Of seventy infants under 1 year of age, forty-eight, or 70 per cent, had prominent costochondral junctions. The accuracy of this examination seemed so questionable that we have disregarded it as of any significance at this early age.

Four infants (5.7 per cent) had slow closing of the fontanel, as evidenced by delayed closing of sutures and posterior fontanel and by the size of the anterior fontanel.

One infant developed moderate flaring of the ribs. Other clinical signs, such as thickening of the wrists, square head, pot belly and bowlegs, were absent. Craniotabes was not noted in any case.

In this entire series, only two blood phosphorus values were below the normal range. Both of these were from infants who were not receiving cod liver oil and who were more than 6 months of age. These low values were accompanied by roentgenograms which showed cupping, spreading and irregularity as did many of the other pictures but differed from the other pictures in that the bones appeared spongy and rarefied.

These irregularities are illustrated in the accompanying pictures. The bones shown in figure 1 have a regular contour and an apparently dense consistency and are typical of the bone development rated as normal by the roentgenologist. The bones in figure 2 are dense, but the distal end of the ulna spreads and there are irregular projections from the radius. The calcium is not being laid down in a symmetrical pattern. These two factors and an increase of density of the lower metaphyses of the radius are typical of the irregularities presented by the roentgenograms of the infants of this study.

Such changes as these took place when the infants were in excellent health, receiving an abundance of milk, one teaspoonful of cod liver oil daily, and making a gain of from 5 to 10 ounces (from 140 to 285 Gm.) a week. Without exception the blood phosphorus values of these infants ranged from 5 to 7 mg. per hundred cubic centimeters.

Figure 3 demonstrates spreading of the ulna and irregularity of the radius but presents a fuzziness or rarefaction not noted in the two previous pictures. This infant came under observation at 6 months of age with a blood phosphorus of 2.9 mg. per hundred cubic centimeters. One other infant of this series presented a similar picture. At 10 months of age this infant had a blood phosphorus value of 3 mg. and the roentgenograms of the wrists showed a fuzziness and rarefaction of these bones. Two and four months previously the blood phosphorus values of this infant had been 6 mg. and the roentgenograms of the wrists showed no decrease in the density of the bones.

One teaspoonful of cod liver oil was added to the daily diet of these two infants, and change in the bones was noted at the end of two weeks. This change consisted of an increase in density and is illustrated in figure 4. The improvement in calcification was steady, though the phosphorus content of the blood did not reach 5 mg. until about four weeks after cod liver oil was instituted.

As the roentgenologist has suggested, it may be that the difference between the slight irregularities of the solid bone shown in figure 2 and the fuzziness evident in figure 3 are differences only in degree of change. If this is true, then practically all of the infants were potentially ricketic and present ideas of protection are scarcely adequate.

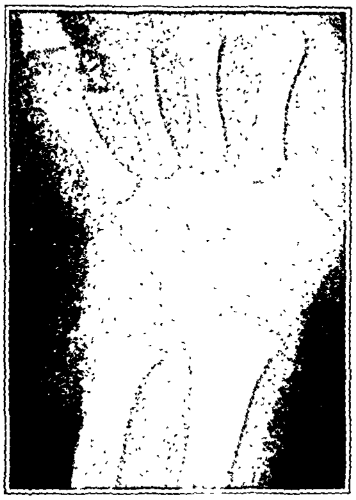

Fig. 2.—Pointing of ulna and irregular projections from distal end of radius.

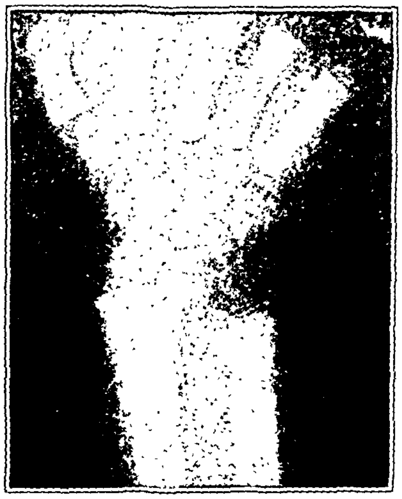

Fig. 3.—Bones of infant 6 months of age. Blood phosphorus 2.9 mg. per hundred cubic centimeters. Note irregularities and rarefaction.

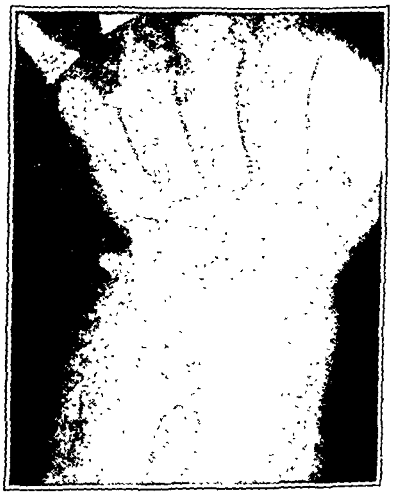

Fig. 4.—Same child as in figure 3, three weeks later. Blood phosphorus 4.1 mg. per hundred cubic centimeters.

We do not doubt that these last two infants had rickets, but we wonder whether any of the others had rickets. Is it a fact that bone growth in a well, rapidly growing, active infant must be symmetrical in order to be nonricketic? The suggestion that irregularities unaccompanied by a decreased density may be physiologic and not pathologic is not altogether original. Dr. Martha Eliot[6] made a similar suggestion several years ago as a result of her survey in New Haven. She reported "slight rickets" before 6 months of age in 85 per cent of the infants observed by her. In our series the percentage is slightly lower than this; 75 per cent of our infants gave roentgenographic evidence of slight rickets before they were 6 months of age.

Numerous surveys of the prevalence of rickets have been made all over the world; and surveys in our own country have placed the incidence of this condition at a high figure. We believe that we are fairly well advanced both in the art and the science of infant feeding but if from 75 to 85 per cent of the infants show a pathologic development of bone during the first year of life there must be something wrong, either with our methods of feeding or with our technic for diagnosis.

---

[6] Eliot, Martha M.: The Control of Rickets, J. A. M. A. 85: 656 (Aug. 29) 1925.

Owing to the number of cases included and the limited period of observation, no definite conclusions can be drawn from this study. However, the data collected up to this point would indicate that the bone growth of well fed, rapidly growing, active infants is not necessarily symmetrical during the first year of life and fails to conform to our standard conception of nonricketic bone development. Whether this is due to the absence of a sufficient quantity of vitamin D or to our present conception of the character of ricketic bone changes is a subject for further investigation.

1073 Madison Avenue.

ABSTRACT OF DISCUSSION

DR. F. C. NEFF, Kansas City, Mo.: I think this study is good for any one who is in the habit of examining roentgenograms of infants. One sees perfectly normal infants sometimes with the fontanel closed at 7 or 8 months. One also sees the fontanel open in perfectly normal infants sometimes 14 to 16 months of age. That is not the rule but it happens sometimes. I have seen a closed fontanel in a Negro baby, aged 12 months, with definite rickets. I have seen the fontanel closed and the child have all the other bone manifestations of rickets.

DR. E. C. MITCHELL, Memphis, Tenn.: Perhaps after two more years of investigation along the same line it may be possible to draw more definite conclusions. It seems to me that statistics on rickets now being given have no definite basis. It is our idea that especially in young children the so-called ricketic changes might be simply physiologic.

ACUTE INTESTINAL OBSTRUCTION *

FRANK SMITHIES, Sc.D., M.D.
CHICAGO

Whatever may be the cause, or (from the duodenum to the rectum) whenever acute, persistent stricture of the lumen of the alimentary tract develops, there is created the gravest form of abdominal emergency.

Initial manifestations, as mild as a common, transient "gas colic," may progress so swiftly that but few hours suffice to accumulate pathologic changes of a degree and extent indicative of early death. Again, abrupt, stormy, painful beginning-symptoms, suggesting rapid and extensive enteric damage, often enough are followed by such quiescence of distress as to present a problem equally puzzling from the points of view of diagnosis and of management. In either type of onset, physical examination of the abdomen may yield few anomalies; the classic or textbook signs of intestinal obstruction are lacking or confused. Indeed, as our material shows, what most commonly are considered as signs of entero or colonic obstruction represent largely the manifestation of chronic, slowly developing types of lesion in which the neuromuscular integrity of the intestine is yet maintained and the mechanical consequences of stenosis are not yet masked or hidden by those evidences of acute, local and systemic intoxication present when obstruction occurs suddenly.

If I may be permitted to introduce certain implied conclusions, before submitting the facts that warrant them, I suggest that the clinical approach to a better understanding of acute intestinal obstruction largely is concerned with the following:

1. Proof that permanent and absolute intestinal obstruction actually exists.
2. Determination at what portion the intestine is involved: (*a*) *high or low jejunum;* (*b*) *high or low ileum;* (*c*) the proximal or the distal colon; (*d*) the small and large bowels together: e. g., intussusception or a union between the two.
3. Appraisal of the degree of structural damage present in the parts involved.
4. Determination of the causes operating to produce the obstruction.
5. Apart from consideration of the mechanical faults and their local pathologic sequelae, an appreciation of what systemic ("toxic," chemicophysiologic) or "constitutional" alterations have accumulated and which themselves introduce grave prognostic as well as therapeutic problems.

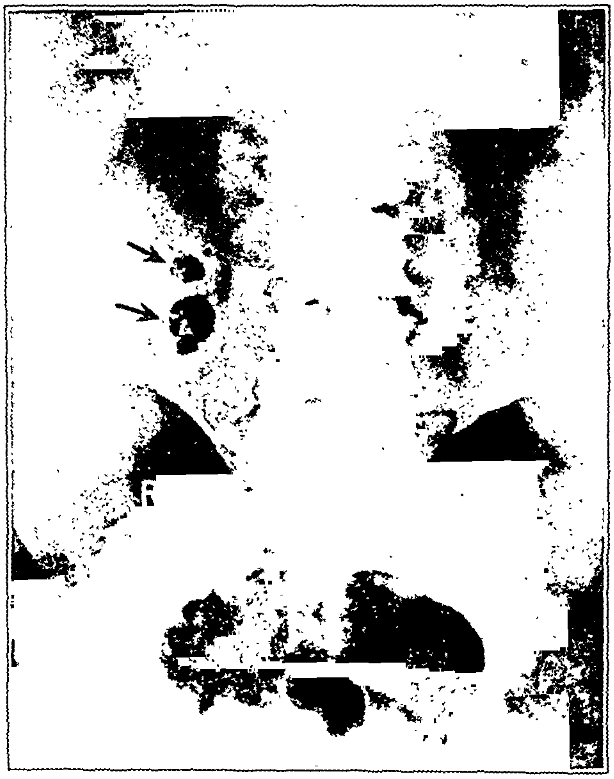

Fig. 1.—Roentgen "scout plate" of acute obstruction of lower ileum with subsequent perforation and, indicated by arrows, large dose of *bismuth subnitrate, given "to control diarrhea," lying free in the peritoneal sac.* The patient was treated expectantly and recovered.

In this series of instances of acute intestinal obstruction, twenty-four patients died (41 per cent). Since such high mortality is possible when there exists the closest teamwork between internist and surgeon, no further emphasis is needed to demonstrate that acute intestinal obstruction is an emergency of first rank and to suggest that at present, perhaps, the situation is not so well handled clinically as it might be. High as is the mortality in this series, it should be mentioned that the mortality is approximately 100 per cent when the condition is not recognized or is diagnosed and treated late. Certainly, lateness in recognition, particularly in the aged, was responsible for numerous deaths among our patients.

MATERIAL

This report summarizes experience with fifty-six patients affected with acute, intestinal obstruction. Fifty-two had abdominal section; two came to autopsy without operation, after perforating; two recovered without operation. In the last two patients, proof of acute intestinal obstruction was adequate, clinically, at the time, and later was proved by roentgen and physical examination. I am indebted to my colleagues, particularly to Dr. Nelson M. Percy of Augustana Hospital, for help and opportunity to study records and operative and pathologic observations.

---

* Read before the Section on Gastro-Enterology and Proctology at the Eighty-First Annual Session of the American Medical Association, Detroit, June 25, 1930.

Space does not permit a complete statistical study of this series; in fact, on this occasion, such seems neither necessary nor desirable. I shall avoid all tabulations but those needed to clarify or emphasize my observations.

There were thirty-five women and twenty-one men in the series. The average age, for the group, was 40.9 years; for women, 48.5 years (a range of from 20 to 68 years), and for men, 31.2 years (a range of from 6 months to 66 years). The patients came from families of moderate circumstances; there were no malnourished or destitute folk on whom any major operative procedures would not be well borne or who, through poverty or ignorance, might not consult physicians when illness appeared. Our mortality of 41 per cent, therefore, does not arise because low intelligence or poverty kept patients away from medical management when first they became ill; doubtless the average charity services of large public institutions would return far higher death rates for like types of lesion in the same age groups. High mortality largely is due to the clinical difficulty of differentiating the early and safely managed stages of acute intestinal obstruction from a host of transient, simple forms of digestive or motor, functional disturbances of the intestine, or of common pathologic processes such as appendicitis, disease of the gallbladder, enteritis, pelvic upsets and the like. In fact, in this series, of those dying, only three patients appeared within 24 hours of the onset of trouble, five from 24 to 48 hours, two within 48 to 72 hours and as many as ten later than 72 hours. Several were as late as 150 hours. Other things being equal, the mortality is in direct ratio to the delay in seeking relief.

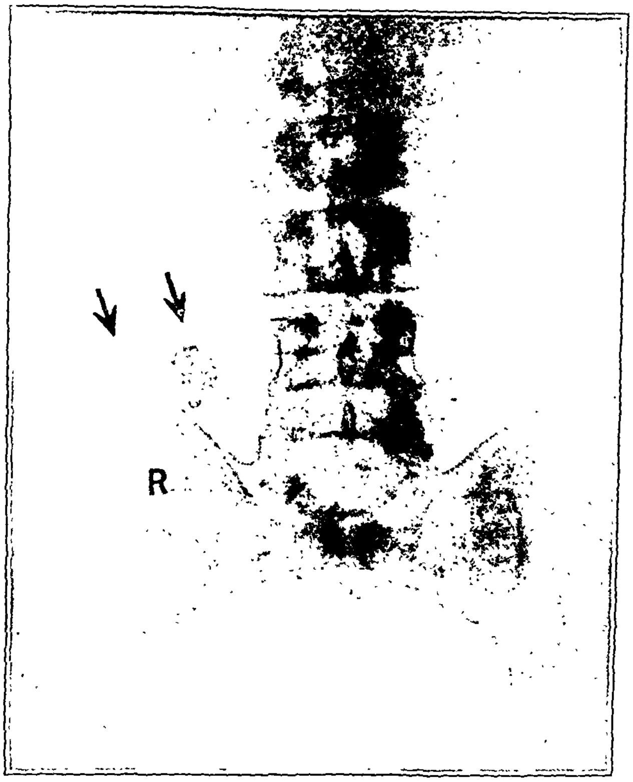

Fig. 2.—Roentgen "scout plate" of same patient as illustrated in figure 1 made five months later showing free bismuth subnitrate, indicated by arrows, lying in peritoneal sac and gradually becoming encapsulated by scar tissue. Patient symptom free with weight gain of nearly 25 pounds (11 Kg.) since initial illness.

CLINICAL PICTURE

1. *Criteria Determining the Existence of Acute, Permanent Intestinal Obstruction.*—These are varied and not so clean-cut as the textbooks suggest. The clinician always should suspect that the "acute abdomen" may mean acute intestinal obstruction and interpret signs and symptoms with that condition in mind, by history, physical and laboratory methods. Then he will have the patient available for management before complications such as peritonitis, perforation or hemorrhage have clouded the picture, or before that state called, loosely, "toxemia" or "acidosis" (recently shown to have peculiar physiologic as well as prognostic significance by experimental surgeons, notably Dragstedt) has supervened.

Within certain limits, the clinical picture also depends on what portion of the bowel is involved. In general, the nearer to the stomach is the obstruction, the more acutely fulminant are the symptoms and the graver is the prognosis. Low intestinal obstruction, even though it is acute in character, gives less dramatic signs of distress, is less virulently toxic, allows longer study and permits a more encouraging immediate prognosis.

The one symptom common to all the patients with this disorder was abdominal pain. It varied in degree, kind and location. Intelligent patients may remember just where the first point of distress appeared; appreciation and consideration of this, roughly, may indicate what portion of the bowel is involved. Usually, the initial pains accompanying small bowel lesions are sharp, cramping or knife-like; they are exhibited in paroxysms. Between the paroxysms, commonly there is diffuse abdominal discomfort. When the lesion involves only the colon, the pain is rarely so paroxysmally exquisite as when the jejunum or the ileum is involved. The normally much slower rate of peristaltic contraction of the colon is not "stepped up" so high in so brief a time. In such circumstances, a greater linear area of smooth muscle is included and the resulting powerful contractile response increases painful tonus less abruptly than when the small intestine becomes acutely obstructed. Hence, the patient with his colon acutely obstructed is rarely found bent double, tossing about in agony and attempting to limit intestinal movements by pressure of the hand on the abdomen or by shallow breathing.

In this series, prostrating paroxysmal pain was the chief initial symptom in 82 per cent of instances of acute obstruction of the small bowel and of 8 per cent of those in which the colon was involved. Of the whole number of patients, these severe "cramps" were a feature of onset in 62 per cent.

Between the paroxysmal pains there appears a relatively comfortable period during which more or less generalized abdominal aching is present. These interim phases are of shorter duration when the jejenum or the ileum is involved than when the lesion is in the colon. This clinical picture persists until the patient is relieved medically or surgically or until such complications as hemorrhage, perforation or gangrene of the bowel occur. The original course of events—so important diagnostically—then is changed by the local signs, and the constitutional reaction caused by the special complication or series of complications appearing in the particular patient. In such circumstances, unless an accurate early history can be secured, often the only diagnosis possible is that of intestinal rupture and an associated peritonitis. How commonly one has to meet this situation is shown by our group of patients: at hospital entrance, twenty-eight patients (49 per cent) were "stretcher cases," twenty-seven (44 per cent) were at the febrile stage, twenty-eight (51 per cent) were in shock, and the average duration of illness for the series was forty-eight hours (women fifty-six hours, men thirty-four hours). It is the presence of these complications, each serious and each confusing the diagnosis, that is responsible in part for the high mortality.

At onset, of almost equal diagnostic value with abdominal pain, well localized, is vomiting with or without nausea. The vomiting is of the nature different from that of other abdominal conditions: it occurs without irritation by food or fluid intake; it occurs with or closely following paroxysmal pain; it may be continuously present from the beginning; often, it is of almost explosive character; it is not rarely profoundly exhausting and, owing to its robbing the body of fluid and the blood of chlorides—particularly the latter phenomenon—may quickly produce a form of "acidosis" leading to early death, in spite of correct diagnosis and most expert surgical procedures.

Through persistent vomiting, secretion of gastric juice rapidly ceases. Moreover, the composition of the blood may quickly be so altered as not to permit again the production of gastric juice. This changed composition of the blood, occurring as a consequence of prolonged vomiting in intestinal obstruction, may determine the outcome. Such emesis, unlike that of pyloric obstruction, is never accompanied by tetany. This different manifestation, when taken in connection with the chemical examination of the blood, i. e., extremely low blood chloride and alkaline radicals and the appearance of high nitrogen or protein substances, is of diagnostic as well as prognostic significance.

The absence of tetany, even were one not to be aware of the underlying cause of the emesis, disposes of the consideration of pyloric stenosis. The continuance of vomiting, without excessive dehydration and without tetany but with absence of gastric secretion and with the blood serum showing low chlorides and carbonates, no marked calcium deviation, but with progressively high nitrogen values, strongly suggests that the obstruction is in the jejunum, perhaps, occasionally in the high ileum, but, very rarely, in the low ileum and practically never in the colon alone.

For these observations credit is due to the surgical physiologists, notably to Dragstedt and to Ivy. It is unfortunate that the practical value of such studies is not more generally known. If, in instances of "acute abdomens," particularly when intestinal obstruction is suspected, carefully performed blood serum studies were viewed with respect to the information they can contribute diagnostically and prognostically, and if correction of these abnormalities of blood serum were an essential part of the scheme of clinical management, a great reduction in mortality would result. All too frequently now, even in clinics of high repute, expert surgical work for the relief of acute intestinal obstruction is seen to go for naught because no preoperative or postoperative observations have been made on the blood serum. Particularly does this apply in that group of patients in whom vomiting has been a major symptom from the onset of the disorder.

Fecal vomiting, provided the patient previously has been on fairly normal diet, is valuable clinical proof of intestinal obstruction. However, if the patient has long been a digestive invalid, his diet may have been far from normal in quantity or kind, and thus he may have a considerable degree of intestinal obstruction without fecal vomiting being exhibited; e. g., in 32 per cent of the patients in this series. When lesions are in the colon or the terminal ileum, fecal vomiting as a symptom may be lacking. Of the thirty-eight patients in whom emesis was markedly present, fecal vomiting occurred in eighteen (47 per cent). Its appearance had certain diagnostic and prognostic significance, as such emesis occurred only when the obstruction was of the jejunum or the ileum; never when the lesion was in the colon. Prognostically considered, 47 per cent of the patients in whom fecal vomiting appeared died within ten days.

To sudden pain and to vomiting, as symptoms suggesting acute intestinal obstruction, should be added acute constipation. Frequently, this may antedate the other symptoms. In a patient whose frequency of evacuation has been normal, when, without change in diet, in habits or in physical or mental routine, absolute constipation appears acutely, intestinal obstruction of some form or degree should be suspected. The suspicion becomes stronger if abdominal pain and nausea appear. In fourteen patients (25 per cent), acute constipation was sufficiently apparent to make an impression on the patient and to bring him under medical observation. When this symptom occurs prominently, most frequently the lesion is in the terminal ileum.

Bloody dysentery was an onset symptom in six patients of this series. It occurred in three, associated with severe acute abdominal pain, well localized in the right lower abdominal quadrant. In these instances the cause of the obstruction was intussusception. Two of the remaining patients were affected with chronic infectious ulcerative colitis, during exacerbations of which, obstruction and perforation of the low ileum took place. The sixth patient was one with cancer of the hepatic flexure of the colon, with perforation, pericolic abscess and acute obstruction.

Masked Signs of Acute Intestinal Obstruction.—The frequency with which patients appear when the actual signs of obstruction itself have become masked by the signs due to sequelae of the acute obstruction (peritonitis, hemorrhage, gangrene of the bowel) makes imperative a careful analysis of the early history. The records only too rarely show observations indicative of obstruction alone or pointing to the place where obstruction actually was. The average patient had been ailing with an abdominal disorder of acute type approximately two and a half days before he came under observation. While such a time factor made easier the diagnosis of well established intestinal obstruction, the clinical picture permitting accurate recognition of the location of the primary fault was clouded.

Most commonly the abdominal picture was that of impending or acute peritonitis. For the series, temperatures averaged 100.5 F. at first examination, with pulse of 95 and respiration 26 per minute. More than half the patients were "stretcher cases." Evidences that a grave disorder existed were apparent in pain-marked features, shallow respirations, the flush of fever, physical and mental restlessness and dehydration of the tissues. Examination of the urine almost invariably disclosed albumin and casts. At entrance, twenty-seven patients (49 per cent) were in shock; 60 per cent were febrile and in thirty-five patients (62 per cent) abdominal distention was marked. Visible peristalsis involving the small bowel was recognized in twelve patients (21 per cent) and that involving the large bowel in two. Free abdominal fluid was demonstrated in seventeen patients (30 per cent), in three instances it being due to cancer. After the initial diarrhea, the absence of bowel movement and the persistence of emesis, with or without intake of food (a caution that not always has been followed) proved characteristic for obstruction. Seven patients had been carelessly subjected to violent catharsis before entering the hospital. Five of these patients did not survive the operative procedure; the strong remedies had brought about rupture.

Determination of the Point of Obstruction.—This can be recognized only grossly even if patients are seen early. The high position of localized, abdominal pain, particularly when this pain is associated with visible, enteric peristalsis, nausea and vomiting, suggests jejunal or ileac obstruction. Intake of food promptly aggravates pain and is followed by emesis. In general, the more quickly emesis follows food intake, the more proximal is the point of obstruction. Food of fluid ingestion is rarely followed by early vomiting when the lesion is in the colon. Pain was far more prompt and more severe on food or fluid intake in enteric than in colon lesions. Rectal feeding rarely caused abdominal pain when the obstruction was in the small bowel except in those patients in whom the obstruction was in the small bowel within three feet of the ileocecal valve, and when the patent valve permitted free flow from the colon into the ileum. In those patients in whom some portion of the colon was adherent to the jejunum or to the ileum, the occurrence of pain on food ingestion or on rectal feeding gave rise to confusing conclusions.

ROENTGEN STUDIES

When acute intestinal obstructions are suspected, roentgen studies are to be condemned if such studies include the employment of barium mixtures. Four patients of this series had had x-ray progress-meals administered after there had accumulated sufficient proof, clinically, that an acute abdominal lesion existed. In all instances, the stimulus of the opaque meal, combined with the weight of the digestively inert barium, resulted in the acute intestinal obstructions being converted into acute intestinal perforations; the barium lay free in the peritoneal sacs (figs. 1 and 2). Only one patient recovered.

At times, certain valuable information may be secured by the roentgen study of the gas-filled loops of bowel. In the films, it may be possible to demonstrate approximately where the obstruction lies; at least, one may state with fair accuracy that the obstruction is in the small and not in the large bowel There are instances in which sufficiently sharp gas shadows are presented to enable the practitioner to make a definite diagnosis of a jejunal, in contradistinction to an ileac, obstruction. If roentgenograms can be made without loss of time and without unduly moving the patient about, they should form part of every routine examination. Not only may these "scout films" give information that is valuable diagnostically, but study of the gas shadows may prove of great help in aiding the surgeon better to plan his operative procedure. When perforation of the bowel already has taken place, and when the patient had previously been taking medicine such as bismuth, the shadow cast by the escaped opaque substance may indicate exactly where the perforation is.

In such circumstances, films serve as cautions against immediate operation. Proof of free-lying bismuth, shown roentgenologically, suggests a waiting policy that may save the patient's life.

PHYSICAL SIGNS

Physical examination of the abdomen is often disappointing should one expect positive information. If the patient is seen very early, a small (intussusception) or a large (cancer or abscess) swelling may be seen at or near the spot where the obstruction is located. This may also be a point of maximum tenderness on palpation. If the patient is not fat, one may at times see or feel peristaltic activity in the bowel proximal to the obstruction.

However, the picture changes so rapidly that on entrance to the hospital very few of the classic or textbook signs of obstruction are present. The abdomen resembles that common to any acute inflammatory process. In this series, abdominal distention was exhibited by twenty-five persons (42 per cent), free abdominal fluid by thirty-one (55 per cent), a mass or swelling more or less well defined by eighteen patients (32 per cent).

Peristaltic movements were not visible so frequently as is commonly assumed; for the whole group of fifty-six patients, they were seen in but eight instances (14 per cent). So-called ladder patterns were observed only three times. The operative observations in patients exhibiting visible peristalsis were: a band across the lower ileum; a band from the low ileum to the navel; intussusception of terminal ileum and ileocecal valve; obstruction of the descending colon; a band from the high jejunum to the stomach; a band from the ascending colon to the jejunum; a band involving both the lower jejunum and the low ileum, and five distinct adhesions between the hepatic flexure of the colon and the jejunum. Bulging navel was noted in six patients (10 per cent).

Certainly, in view of the definite and often extensive pathologic condition demonstrated at operations or at autopsy, the physical examination of the abdomen disclosed little of a "characteristic" nature. Indeed, our correct preoperative diagnosis of acute intestinal obstruction (forty-seven instances, or 84 per cent) would not have been possible had we relied only on the examination of the patient and had we disregarded a careful step-by-step history of exactly what happened symptomatically from the beginning of the illness.

As I have mentioned, fifty-two patients experienced abdominal section: two were hopeless as surgical risks, being practically moribund on entrance; two were so ill that laparatomy was deemed not wise. These two went on to perforation, localized abscess, were desperately ill, but made complete recovery in nine and fourteen weeks, respectively. In both instances the obstruction involved the ileum. The outcome of these two patients would appear to indicate that, oftener than is suspected, acute obstruction of the low ileum, where the surgical risk is great, might be treated best expectantly. If the shock of perforation is survived and the infection can be localized, spontaneous short-circuiting takes place and recovery is possible.

NATURE AND LOCATION OF THE OBSTRUCTION

In this series, the causes of the acute obstruction were considerably varied. It is interesting to note that, prior to the acute obstruction, more than 60 per cent of the patients already had had from one to as many as seventeen abdominal operations. The effects of these operations were important in the later production of acute obstruction.

Commonly enough to give the impression that previous abdominal operations were responsible for later acute obstructions was the incidence of "bands" and adhesions in the production of the disturbance. However, since Bryant has shown how frequently omental, mesenteric and intravisceral bands or adhesions are present in the embryo and the new-born, one must be cautious in ascribing the presence of such obstruction-producing agents to previous surgery.

In this series, acute obstruction from bands and adhesions occurred in forty-four patients (79 per cent). Their most common site was in the right lower quadrant, affecting the ileum most frequently. The mid and upper jejunum was next in point of frequency. Then followed in order the sigmoid, the transverse and the ascending portions of the colon. Volvulus was observed in the ileum or the jejunum five times; intussusception (through the ileocecal valve) twice; hernia of the ileum through the broad ligament three times; involvement of the ileum with the ovary and tube, three times; cancer, perforating and followed by abscess which involved the lower ileum or the jejunum, three times; acute ileus, twice; ulceration of the ileum with perforation and obstruction, three times; adhesive obstructing bands from the viscera (gallbladder, stomach, spleen, liver) six times; mesenteric thrombosis, once.

The obstruction was so acute and so complete that gangrene complicated the operative procedures, requiring resection of the viscera, in thirteen cases. The mortality was 85 per cent in this group in spite of prompt action, skilled surgery, blood transfusions, draining the proximal portion of the affected intestine and all known forms of supportive treatment. Those patients who had been given strong cathartics before entering the hospital fared particularly poorly. Certainly, in all patients in whom usually the bowels have moved normally, the appearance of acute constipation, with nausea and with or without nausea or vomiting, contraindicates catharsis: simple enemas are often a life saving measure and usually give comfort.

MANAGEMENT

While all patients in whom acute intestinal obstruction is diagnosed or is suspected are immediately or, potentially, surgical subjects, the internist may be of help in sending the patient to the surgeon as a reasonably good operative risk. Mouth feeding should be interdicted, gastric or intraduodenal lavage by the Rehfuss tube (introduced by a stiff wire stylet) begun early, catharsis forbidden and fluid (physiologic solution of sodium chloride or Ringer's solution) given into the colon by rectal drip and constantly. Abdominal examination, made early and often repeated, may locate the place of obstruction and give information relative to the occurrence of gangrene, perforation or abscess. "Scout films" should be made whenever possible; study of the gas shadows may prove of great importance in locating the obstruction, giving information as to the degree of proximal dilatation, indicating a perforation or aiding the surgeon in planning operative procedure. The leukocytes should be counted hourly; an ascending count, with frequent and thready pulse, means extension of inflammation and a bad prognosis. So, also, does a lowered count, when the leukocyte response had originally been brisk, particularly when accompanied by a drop in temperature and rise in pulse, but a fall in blood pressure. Peristalsis should be stopped by injections of morphine, preferably given intravenously when shock is present. Locally, if perforation or gangrene is suspected, attempts should be made early to localize the pathologic condition by the application of ice bags. If perforation has not taken place, large, hot dressings saturated with alcohol and boric acid should cover the abdomen.

As early as possible, studies of the blood chlorides, carbonates, calcium and nonprotein nitrogen should be made, particularly in the presence of constant regurgitation or vomiting. Falling of the alkaline radicals with increase of the nitrogenous bodies indicates a bad prognosis unless there is prompt and vigorous attempt made to counteract the phenomenon by continuous administration (preferably, intravenously) of solutions of sodium chloride and sodium bicarbonate or Ringer's solution. This procedure often is a life saving one, whether instituted before or after surgery or both.

And, finally, from the beginning, the internist should be in the closest cooperation with a skilled, conservative and scientifically trained surgeon.

920 North Michigan Avenue.

ACUTE INTESTINAL OBSTRUCTION *

IRVIN ABELL, M.D.
LOUISVILLE, KY.

The most important single factor in the clinical consideration of acute intestinal obstruction is the element of time; a second one of great moment is offered by the site and character of the obstruction, whether high or low, the former pursuing a more rapidly fatal course than the latter. The precise significance of these two factors becomes apparent with a full realization of the sequence of events common to all types of acute intestinal obstruction; namely, mechanical obstruction of the intestine with stoppage of the fecal current, damage to the bowel wall with ultimate gangrene and peritonitis, and an associated production of toxins often of the most virulent type. The high mortality that has obtained and still obtains in the treatment of intestinal obstruction is a serious indictment of both diagnostic ability and surgical initiative.

A study of accumulated statistics reveals what is common knowledge, to wit, that, while acute intestinal obstruction carries an inevitable mortality, the greater portion of the mortality may justly be attributed to delay in recognition and to tardiness in the institution of appropriate surgical treatment. The research workers by their physicochemical studies of the body fluids have afforded much valuable aid in the appreciation of the changes in body chemistry with the indication of means to assist in the restoration of the latter, but the underlying fact, with which all adjuvants must be correlated, is that the obstruction is mechanical and must needs be corrected mechanically. The solution of the problem in the early hours following the advent of obstruction, when but simple obstructions are present, may require nothing further: the mortality is low and the results are

---

* Read before the Section on Gastro-Enterology and Proctology at the Eighty-First Annual Session of the American Medical Association, Detroit, June 25, 1930.

brilliant if the obstruction is relieved before the wall of the bowel is compromised by pressure or strangulation, volvulus or thrombosis. With the incidence of the complications dependent on strangulation and toxemia, which invariably follow the continued presence of the obstruction, the relief of the obstruction becomes but one of the indications to be met and the risk of any operative procedure is enormously enhanced.

Since early detection is of such overwhelming importance, I cannot forbear stressing the points leading to a diagnosis, even at the risk of being tedious from reiteration of that which has already been presented. Unfortunately, an attitude of ultraconservatism in diagnosis, awaiting the onset of symptoms that prove the presence of obstruction but also indicate the approach of dissolution, has been, if not the accepted rule, then one quite commonly followed. It is an unpardonable mistake to spend invaluable time in making differential diagnoses when symptoms of an abdominal emergency are evident. The presence of abdominal pain, vomiting and constipation with an absence of fever and leukocytosis should put the burden of proof on the medical attendant to show that no obstruction exists. The history, particularly if previous abdominal ailments are indicated, the physical examination, the presence of active peristalsis, visible or audible, with the flat roentgenogram interpreted by a competent radiologist, in addition to the three cardinal symptoms mentioned, should permit of a working diagnosis before the accession of fever, leukocytosis, distention and paresis indicates changes brought about by strangulation, and chemical examination of the blood shows profound alterations. Morphine and purgatives, as characterized by Haggard, but compound the felony of delay. The former, with its relief from pain affording the patient a false sense of security, denies him the relative safety which early operation offers and lets him drift into the dangers of delay, while the latter merely increases the damage which an already active peristalsis inflicts.

The principles underlying the surgical treatment of acute intestinal obstruction may be discussed under three headings: the preparation of the patient, the operation, and the postoperative treatment.

PREPARATION OF PATIENT

The preparation of the patient will of necessity depend on the condition presented at the time of coming under observation, which in turn will depend on the location of the obstruction and the duration of its existence. If the duration of the obstruction has been short and the vomiting not excessive, the routine preparation for abdominal section will suffice with the added precaution of emptying the stomach and rectum, if perchance the latter has escaped the repeated enemas given as routine. When the vomiting has been excessive, which it usually is when the obstruction is situated high in the small bowel and when the duration of the obstruction has permitted the development of toxicity and dehydration, operation should not be undertaken until measures looking toward their correction have been instituted. The blood of such patients will show a decrease in the blood chlorides with a rise in its carbon dioxide combining power and a coincident rise in the nonprotein nitrogen and urea. The lost chlorides should be replaced with sodium chloride in solution, both subcutaneously and intravenously, from 1 to 2 per cent solution for the former, and from 3 to 5 per cent solution for the latter method of administration. In both instances it should be given slowly to prevent pain and, as well, damage to the tissues with which it comes in contact. Orr, with whose name much of the splendid blood research work in intestinal obstruction is connected, is of the opinion that the sodium chloride not only restores the normal balance in the blood but also acts as a definite therapeutic agent in overcoming the abnormal chemical changes found therein. Water should be given in abundance, subcutaneously and intravenously, to overcome the dehydration and, in those patients in whom starvation is evident, nourishment is to be added in the shape of dextrose. The technic of venoclysis as devised by Hendon, consisting of a special needle and fluid container, permits of a simple and satisfactory method for the continuous intravenous administration of fluids, water, saline solution, dextrose and citrated blood; the needle may be kept in the vein without change for as long as five days and the character of the fluid in course of administration may be changed at will. Blood transfusions in depleted patients are of definite help and may be given by this method with the least annoyance to the patient.

OPERATION

The cure of acute intestinal obstruction depends on the removal of the obstruction by surgical operation. The operation in simple obstruction may likewise be simple, while with strangulation and toxemia it can never be so classified. The three main objectives are: (*a*) the removal of highly toxic material from the intestine proximal to the obstruction; (*b*) the relief of the distention that is paralyzing the intestinal musculature, and (*c*) the restoration of the continuity of the intestinal lumen with the reestablishment of the fecal current. The external obstructions are both visible and readily accessible, their one feature presenting at times a difficult problem being the management of the damaged intestine. If a portion of the intestine is not viable, resection is imperative provided the condition of the patient will withstand this amount of operative trauma: if plainly prohibited or if the gravity of the patient's condition is such as to make the wisdom of resection a matter of doubt, the gangrenous bowel should be amputated and the divided ends anchored outside the abdomen—shotgun barrel enterostomy—to be closed later when local and general conditions have improved to the extent of making the operation reasonably safe.

With internal simple obstructions involving the small intestine, the complete operation may be and should be carried out. In cases of advanced obstruction of the small intestine which have not reached the stage of gangrene but in which the circulation of the proximal segment has been impaired by the distention due to the imprisoned gases and toxic fluids, a fertile field is offered for the display of surgical judgment and craftsmanship. The distended intestine makes intra-abdominal manipulation difficult and often renders the recognition of the pathologic anatomy perplexing, while the friability of the bowel wall due to distention with impairment of circulation both at and above the site of strangulation makes anything other than the gentlest handling a matter of great hazard. Evisceration as a routine in such cases is contrary to sound surgical practice, it being a maxim that the less manipulation the greater the percentage of recoveries. However, I have not hesitated to employ evisceration in those cases in which the visualization and accessibility of the site of obstruction made it necessary. After the obstruction has been released, the distended intestine is emptied of its septic and toxic contents before it is returned to the abdomen; thus the necessary drainage of the distended bowel is accomplished and at the same time its return to the abdominal cavity is facilitated. The enterostomy opening may be closed or utilized for a more prolonged drainage as the exigency of the case may require.

In the advanced cases presenting dehydration, starvation and toxicity, the institution of appropriate measures for their correction still leaves the surgeon in a quandary in making a choice between the liberation of the obstruction with drainage of the distended intestine and being content with the latter procedure alone. Many lives have been saved that would otherwise have been lost, by the performing of a jejunostomy or enterostomy near the site of obstruction under local anesthesia, the release of the obstruction being reserved for a later date when the absence of toxicity and a return of the bowel wall to its normal integrity make the necessary operative manipulation both safer and easier. It would seem that better drainage is obtained with the lower enterostomy and that it is more susceptible of spontaneous closure than jejunostomy. The stomach and duodenum can be effectively kept empty by an indwelling gastroduodenal tube. The employment of enterostomy alone is quite naturally reserved for the more desperate cases and offers no opportunity for determining the character of the obstruction or the condition of the intestine at the site of obstruction. Should the bowel be gangrenous, death from peritonitis is inevitable, since resection or amputation with the formation of a gun barrel enterostomy offers the only opportunity of averting such an issue.

When the site of the obstruction is in the large bowel, granting that the lesion is not one productive of gangrene such as volvulus or hernial strangulation, enterostomy is the primary treatment of choice. Obstructions in the colon are devoid of the acute toxic manifestations noted with those situated in the small bowel, although the sequence of stoppage of the fecal stream, strangulation, gangrene and peritonitis are much the same, if of slower progress. The disparity in size between the large and the small bowel makes for difficulty in anastomosis, while the edema and vascular changes in the colon proximal to the obstruction greatly hamper accurate suturing and correspondingly increase the danger of leakage. The latter impediments are in large measure removed by preliminary drainage, the secondary operation then becoming one of election. In the event of gangrene of the colon, resection, if within the limit of sound surgical judgment, should be practiced; otherwise sequestration of the gangrenous segment outside the abdomen with low ileac enterostomy as a primary procedure followed by restoration of bowel continuity at a later date. The selection of the anesthetic will depend on the character of the proposed operation. Jejunostomy, low enterostomy and cecostomy are readily and best accomplished under local anesthesia. Muscular relaxation is essential for careful and accurate intra-abdominal work, particularly in the presence of intestinal distention and fragility: gas-oxygen with sufficient ether to overcome muscle rigidity meets these requirements. As spinal anesthesia, by suppressing the inhibitory action of the spinal cord, permits excitatory action of the ganglions and promotes intestinal peristalsis, its use has been suggested in paretic ileus. In those cases in which an enterostomy has been done in the course of an advanced obstruction and in which the paresis from distention prevents drainage of more than the coil into which the enterostomy tube has been inserted, the injection of a spinal anesthetic or—what is safer and experimentally accomplishes the same result—blocking of the splanchnic nerves, may be of distinct benefit. It has also been suggested that spinal anesthesia will differentiate between mechanical and paralytic ileus; if, within fifteen minutes after the injection of the spinal anesthetic, passage of gas and feces and disappearance of distention is not obtained, enterostomy should be performed immediately; thus advantage may be taken of the anesthesia already produced.

POSTOPERATIVE TREATMENT

Vomiting is controlled by intermittent gastric lavage or by an indwelling gastroduodenal tube, the patient drinking water as desired, the unabsorbed portion of which returns through the tube without causing any discomfort. The body fluid and nutrition balance is maintained by subcutaneous and intravenous administration of saline solution and dextrose until such time as the resumption of normal peristalsis permits of oral administration. When an enterostomy has been performed it is essential to see that drainage occurs; this can be promoted by hot fomentations to the abdomen, saline irrigation of the intestinal lumen through the enterostomy tube and the cautious administration of solution of pituitary hypodermically. These failing, splanchnic blocking or spinal anesthesia should be tried. When no enterostomy has been done, colonic irrigation is employed in connection with the measures before mentioned to take care of the distention. It may be said in conclusion that while serologic research, choice of operative procedure and refinements in technic have contributed to a worth-while reduction in the mortality of acute intestinal obstruction, the greatest hindrance to its further reduction continues to be the delayed operation.

321 West Broadway.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. SMITHIES AND ABELL

DR. JAMES T. CASE, Chicago: What Dr. Abell said about the element of time is of the greatest importance, as we all recognize, lest we await the appearance of symptoms of an impending postmortem rather than symptoms of an early diagnosis of acute intestinal obstruction. I do not quite agree with Dr. Smithies when he says that barium should not be used; however, the so-called scout film should also always be used first, because from the appearance of the intestinal gas and its position in the abdomen one can gain a great deal of definite information. The fact of obstruction is the chief thing of interest. Is there, or is there not, acute intestinal obstruction? If there is, there is only one thing to do, and the sooner it is done, the better. In a case of ileus, the surgeon at the operating table expects to find the dilated intestines when he opens the peritoneum. It is perfectly possible to determine the presence of dilated intestines before operation, and that can be done by the flat film or scout film with no more trouble than is required to change a sheet or to use a bedpan. The patient is lifted by the drawsheet, an x-ray film holder slid under him, the x-ray portable apparatus brought to the bedside, and an exposure of one or two seconds made. The patient has been disturbed but slightly. The film can be developed to make a 14 by 17 inch map, and on that map one can measure intestinal coils filled with the gas which is naturally there in cases of ileus; it is easy to make a relatively accurate estimate of the diameter of the intestinal coils and to say whether the gas area represents the small or the large intestine. So, it is possible in the great majority of instances, without opening the abdomen, to determine the presence of dilated intestinal coils. If the characteristic herring-bone or feathery appearance of the shadow due to the small intestinal folds is not apparent, then I believe it is perfectly feasible to give a small quantity of barium in a dextrose-water mixture by mouth; it is surprising how soon that will visualize the small intestine so that it can be recognized by another film made four or five hours after the administration. Occasionally a little longer time is required. If the gas is in the colon, one is justified in making attempts to empty the colon by an enema. I never use the opaque material in a case of suspected obstruction of the small intestine until after I have made the scout film; generally there is no necessity of giving a regular meal, for a small quantity of barium sulphate will serve the purpose. Except when an intestinal anastomosis has been done, I do not fear to give a small amount of barium in a dextrose-water mixture.

Dr. Thomas G. Orr, Kansas City, Mo.: In discussing intestinal obstruction, I am conscious of the fact that a mechanical situation which requires surgery is being dealt with and that this is really the important feature, after all. Without surgery, one cannot hope to obtain a cure because of the true mechanical nature of the condition. Paralytic ileus is a different problem and can be relieved without surgical measures in some cases. In the consideration of intestinal obstruction, three events have taken place in the last few years which are quite significant. The first is the chemical study of the blood. There has been found a decrease in the chlorides, an increase in the nonprotein nitrogen, and in most cases of high intestinal obstruction an increase in the carbon dioxide combining power. I do not know what Dr. Smithies' experience has been when he mentions acidosis in connection with these cases. In my experience, if there has been any change, there was an alkalosis. Next in importance is the fact that the upper intestinal tract secretions are extremely important in maintaining life. It has been definitely proved that drainage of the stomach and the duodenum and jejunum will produce death in a few days in experimental animals; therefore, there is something in the upper intestinal juices essential for life. The third joint is an explosion of the old idea that drainage of the so-called toxic materials proximal to the obstruction into the bowel below the obstruction will kill the patient. I do not believe there is anything to that at all; in fact, I think the contrary has been proved, that it would be nice if one could have all of these fluids drained into the normal bowel below to maintain life. This belief is substantiated by the work of Raine and Perry, and White and Fender, and by Wilkie. When doing an enterostomy, it is doubtful whether the chief factor is a drainage of the toxic material from the bowel, but rather a relief of distention in the bowel. In order to obtain results from operation or any treatment, one must get these patients before peristalsis has been abolished. If an enterostomy is done and the bowel is paralyzed, there will be no results. If there is no peristalsis, there is no work, and nothing is accomplished either by the removal of an obstruction or by the doing of an enterostomy. I agree with Dr. Case that enterostomy is indicated in some cases.

Dr. Roy D. McClure, Detroit: Twenty-three years ago I read a paper on the experimental production of intestinal obstruction. At the end of the symposium the consensus was for earlier diagnosis and earlier operation. Today the conclusions to be drawn from the papers of Dr. Smithies and Dr. Abell are much the same as the conclusions drawn twenty-three years ago. Some advances have been made. One of the greatest is in the use of sodium chloride, as advocated by Dr. Haden and Dr. Orr. Their work on sodium chloride has been outstanding. I agree with Dr. Smithies—a patient whom one suspects of having intestinal obstruction should be worked up to the limit as far as present knowledge is concerned as to the chemical condition of the blood, and perhaps roentgenograms should be taken. This can usually be done quickly and I agree with Dr. Abell that there should be no unnecessary delays. I believe that the medical man and the surgeon should both see and follow through with the patient suspected of having intestinal obstruction until the patient is at least over the crisis of obstruction. Dr. Abell mentions the type of anesthesia to be used. I have been using spinal anesthesia with increasing frequency. Where any considerable manipulation of the viscera is necessary there is less postoperative distention than I formerly had with general anesthesia. Postoperative distentions sometimes went on to a paralytic ileus, because the bowel was so paralyzed by the preparation given. In the service I had in a New York hospital a little over twenty years ago, a preparation for any major operation was used which was extremely damaging to the intestinal function. The patient was given 2 grains (0.13 Gm.) of mild mercurous chloride, half a grain every half hour for four doses with 10 grains (0.6 Gm.) of sodium bicarbonate followed in the morning by magnesium sulphate. After his bowels moved he had an enema. During the night he had a soap enema and in the morning a sodium chloride enema. Postoperative distention was the rule. Today, without preoperative cathartics, postoperative distention is almost nil compared with what it was then. So, paralytic ileus is less frequent. Prophylaxis against intestinal obstruction is as possible as in some of the other diseases. Polyps, benign or malignant, carcinoma, ulcers and constricting adhesions can be diagnosed and treated early before obstruction develops.

Dr. Walter A. Bastedo, New York: I wish to emphasize two points. In the recent past I have had two cases of obstruction from femoral hernia, both in elderly women, one of them 83. In each case at least five days had elapsed since the first pain came on. In the 83-year-old woman, it had been seven days since the first pain came on, and five days since the last feces had been passed. There was evidently obstruction, and as the patients were so old, I supposed that they might have carcinoma. Both were fat and tremendously distended and it was difficult to recognize anything. Their abdomens were tender everywhere, but on palpating in the routine way in one patient I found a little femoral hernia on the right side. There was a delay of twenty-four hours in operation because others would not agree, and the patient died. In the 83-year-old patient the hernia was on the left side. I was not sure of it but there was great tenderness at the femoral region, and I thought a hernia probable. The surgeon in that case thought it was the more usual splenic flexure carcinoma and made the cut high up, but after going in high up he found he had to make a second cut, which he might have avoided if he had realized or thought with me that perhaps there was a femoral hernia. The patient made a complete recovery. The other point I want to speak about is this: If the physician fools around with these patients a little overlong and then calls a surgeon, he can hardly expect him to agree with him at once, on seeing the patient for only fifteen minutes and talking with him. The surgeon should be brought in early so that he can see the patient two or three times. Over and over again, I am sorry to say, with the most eminent surgeons, I have had a delay of twelve or twenty-four hours because at the first visit it was impossible for me to convince the surgeon of the diagnosis.

Dr. Owen H. Wangensteen, Minneapolis: Forty-one years ago when the treatment of intestinal obstruction was discussed at the German Congress of Internists convened at Wiesbaden, Fürbringer stated that the mortality of medical treatment of acute bowel obstruction was 66 per cent—a mortality no higher than with surgical treatment. A year previously, the same topic was the subject of a symposium in which Reginald Fitz and Nicholas Senn presented the medical and surgical aspects, respectively. A mortality of 70 per cent for both types of treatment was reported. It was agreed that, after two days of medical conservative procrastination, patients with acute bowel obstruction should have the benefit of what little surgery had to offer. Today, although it is universally acknowledged that patients should be operated on as soon as the diagnosis is made, the general mortality is almost as high as it was forty years ago. What is most needed is a better understanding of the early criteria on which a diagnosis can be made. It is significant that simple bowel obstruction is the only abdominal disaster that presents early no local physical conditions suggestive of the presence of a serious intra-abdominal lesion. Strangulation obstructions, because of the infarction of the bowel, of course produce abdominal tenderness and rigidity. In a patient, complaining of intermittent crampy abdominal pain followed by nausea and vomiting, who exhibits no local physical conditions, simple bowel obstruction should be suspected. A physical sign of great importance in the diagnosis, not mentioned by either of the authors, is auscultation of the abdomen. It is my experience that peristalsis is usually visualized only in subacute or chronic obstructions; but loud intestinal borborygmi may be heard with the stethoscope, and, if dilated coils are present, sounds of metallic character are often made out, a finding almost pathognomonic of bowel obstruction. If a single plate is made of the abdomen and gas is seen in the small intestine, the diagnosis of acute bowel obstruction is established. Gas is normally present throughout the intestinal canal, but in adults it is visualized normally only in the stomach and colon; the intermixture of gas and fluid is so intimate in the small intestine that gas is not visualized on the roentgenogram. Gas in the small intestine is therefore synonymous with intestinal stasis.

SIGMOIDOSCOPY VERSUS X-RAYS IN THE DIAGNOSIS OF TERMINAL BOWEL DISEASE *

FRANK C. YEOMANS, M.D.
NEW YORK

During the period of thirty-five years since Professor Roentgen discovered the x-rays and Howard Kelly introduced standard rectoscopes, refinements in the technic of roentgenology and improvements in proctoscopes have made these two agents prime factors in the diagnosis of gastro-intestinal diseases. Each method has its indications, advantages and limitations, and frequently the two are mutually helpful in reaching a correct diagnosis.

The roentgen ray has a wide range of applicability and has proved its value in the diagnosis of gastro-intestinal lesions, notably in the movable portions of the tract, as the stomach and colon; in demonstrating position, contour, function, points of stasis and defects indicating pathologic changes. In the relatively fixed rectum and distal sigmoid colon, however, which are situated largely within the bony pelvic girdle, the x-rays are of comparatively limited value. Prominent defects are that:

(*a*) An important lesion may be missed entirely.

(*b*) Although the site and apparent extent of a lesion are discovered, especially if it is of a stenosing character, its nature is frequently not disclosed.

(*c*) In many cases, interpretation of the image is so uncertain as to cast grave doubt on the diagnosis.

The x-rays are now so generally available that all too frequently when the patient presents symptoms referable to the distal bowel the physician at once refers him for a gastro-intestinal series. This is unfair to both the patient and the roentgenologist. It deprives the latter of invaluable data and frequently imposes on the patient loss of time and the expense of a prolonged indirect search for what can be directly felt or seen. Moreover, the nature of an accessible lesion frequently remains in doubt and serious conditions at their onset are easily misinterpreted. For example, amebic colitis in its early stages or before secondary infection of the ulcers has occurred may present the same symptoms and roentgen appearance as ulcerative colitis but, viewed through the proctoscope, the early lesions are characteristic and pathognomonic. A smear from a typical ulcer, examined at once on the warm stage of a microscope, reveals motile amebas and clinches the diagnosis.

On the other hand, a negative roentgen report, as for example in the case of a small tumor, instils a false sense of security. Meanwhile the lesion that was missed develops apace and the most favorable time for its treatment is lost. This is evidently due to the fact that an insufficient number of men are being trained to do a competent proctosigmoidoscopy and to interpret the observations. To correct this deficiency every hospital and diagnostic group should have associated with it a trained and competent proctologist.

Without in the least disparaging the diagnostic merit of the x-rays, my purpose is to stress that in examination of the terminal bowel the usual order of procedure should be reversed, sigmoidoscopy being first in order. Endoscopy usually establishes the diagnosis of lesions in the rectum and the pelvic colon. When the observations are negative or if the pathologic condition found seems inadequate to explain the symptoms, a roentgen study should always follow the endoscopy. Even negative endoscopic observations are valuable data for the roentgenologist.

The important reason for emphasizing early endoscopy is that the vast majority of pathologic lesions of the large bowel are limited to or involve the rectum or pelvic colon; namely, practically all cases of simple colitis; the specific infections—amebic, bacillary and gonorrheal; 90 per cent of organic strictures; 70 per cent of nonmalignant tumors, and 75 per cent of large bowel carcinomas.

The x-rays comprise the best available agent for determining the extent of involvement in ulcerative colitis and in detecting tuberculosis of the cecum; it is our chief reliance in demonstrating diverticulosis of the colon and especially diverticulitis of the sigmoid, and rarely it may discover a double primary carcinoma in different colonic segments.

Digital examination should always precede rectoscopy. Nothing else is so conclusive as palpation for organic lesions of the lower 8 to 10 cm. of the rectum and it is the only means of detecting lymph node recurrence of carcinoma beneath an intact mucosa.

A satisfactory proctosigmoidoscopy implies introduction of the tube into the pelvic colon, which can be accomplished in more than 70 per cent of cases. The normal anatomic limit of advancement is the apex of the sigmoid loop, which varies from 10 to 14 inches from the anus. Standard textbooks on proctology give the correct technic of sigmoidoscopy but, naturally, as in esophagoscopy or cystoscopy, experience is essential for correct interpretation of the pathologic changes revealed. Requisite to obtain the full benefit of bowel endoscopy are calibrated tubes of various lengths and diameters, electrically lighted and fitted with an eyepiece for air inflation when needed.

In stenosing lesions, such as strictures or neoplasms, the tube of one-half inch diameter can usually be passed without difficulty through the lumen to the uninvolved area above, thus determining at once their limits. If painful lesions of the anal canal with sphincteric spasm are present, the tube of small diameter is imperative for successful examination unless the parts are first anesthetized by a topical application or by local infiltration.

The dangers of injury or perforation of the bowel wall can always be avoided if the tube, after passing the anal canal, is advanced, as it should be, under guidance of the eye in the axis of the bowel lumen, aided by atmospheric pressure and, when necessary, by light puffs of the pneumatic bulb.

Important data obtainable by proctosigmoidoscopy are:

1. Reaction of the bowel contents.
2. Condition of the mucosa; atrophic or hypertrophic catarrh.
3. Infections; amebic, bacillary, hemorrhagic, gonococcal, and chronic ulcerative colitis (nonspecific).

---

* Read before the Section on Gastro-Enterology and Proctology at the Eighty-First Annual Session of the American Medical Association, Detroit, June 26, 1930.

4. Ulcers; tuberculous, syphilitic and the large solitary (callous) ulcer.
5. Stricture; fibrous or inflammatory.
6. Nonmalignant growths; number, situation, distribution and character.
7. Malignant tumors, most commonly adenocarcinoma, and their extent of involvement.
8. Invagination of the pelvic colon into the rectum (third degree prolapse of the rectum).
9. The nature of a rectosigmoidal constriction, whether inflammatory or malignant, and whether intrinsic or extrinsic.
10. Discovery of amebas, when present, from material collected on sterile swabs and examined immediately. This material is available for smears and cultures from which autogenous vaccines may be made.

If doubt exists as to the precise nature of an ulcer, stricture or neoplasm, *biopsy* should be done forthwith and the site of removal treated with 95 per cent phenol followed by alcohol. The data thus obtained are of prime importance in the diagnosis, prognosis and rational treatment.

The following cases are cited briefly for illustration. The roentgen studies and reports were made by thoroughly competent roentgenologists.

REPORT OF CASES

Case 1.—W. M., a man, aged 44, during the three weeks previous to examination had dull pain in the lower part of the abdomen and occasionally had some fresh blood in the stools, which occurred once daily. A series of roentgenograms that had been made during the injection of barium showed a spotted appearance of the barium in the lower part of the sigmoid; there was suggestive evidence of polypi of the lower part of the sigmoid. Abdominal palpation showed a tender sigmoid loop; sigmoidoscopy to a depth of 13 inches disclosed no polypi or ulcers but a congested, beefy mucosa (colitis), which cleared up promptly under treatment. The spotted appearance was evidently due to the irritability of the involved segment.

Case 2.—G. H., a man, aged 65, was admitted to the hospital with the diagnosis of intestinal obstruction. At about the middle of the sigmoid or just above its junction with the rectal ampulla was a long jagged defect. Differential diagnosis between carcinoma and abscess could not be made. The observations indicated a definite organic lesion. The rest of the colon filled poorly with barium. Sigmoidoscopy showed at 7 inches above the anus a pedunculated tumor the size of an almond, which was removed with the electric snare and proved on histologic examination to be an adenoma.

Case 3.—H. D., a man, aged 66, during the four months previous to examination averaged six stools daily, with some fresh blood at intervals. In the roentgenograms made after evacuation of the barium enema, two polypi, one on the right and one on the left side, at the junction of the sigmoid and rectum, were shown fairly distinctly. These were not shown at all when this part of the colon was completely filled with barium. Digital palpation and proctoscopy showed two polypoid growths just above the anal ring on the anterior rectal wall, the base of the larger being 3 cm. long by 1 cm. broad. The rectum above this point and the pelvic colon were normal.

Case 4.—A physician, aged 73, always in good health but constipated, had a sudden intestinal hemorrhage two days before examination. Sigmoidoscopy at this time disclosed at a depth of 8 inches an early ulcerated neoplasm, biopsy of which showed adenocarcinoma. Roentgenographic and fluoroscopic study of the gastro-intestinal tract revealed multiple diverticula of the sigmoid, and incomplete stricture at the lower end of the sigmoid, the involved area being about 4 cm. in length, a portion of involved sigmoid wall at this place retaining power of contraction. These changes were those exhibited in a scirrhous type of new growth. The roentgenograms demonstrated the diverticula. This case illustrates in a striking manner the diagnostic value in certain instances of roentgenograms combined with sigmoidoscopy.

CONCLUSIONS

1. Sigmoidoscopy is indicated and should be performed in every case presenting intestinal symptoms.
2. Sigmoidoscopy usually gives more accurate and precise data in diseases of the rectum and pelvic colon.
3. Obtainable data frequently establish a correct diagnosis promptly, which is an economy for the patient and gives valuable information to the roentgenologist.
4. Endoscopy should precede the roentgen study.
5. Every general hospital and diagnostic group should include a competent proctologist on its staff.

171 West Seventy-First Street.

ABSTRACT OF DISCUSSION

Dr. John L. Jelks, Memphis, Tenn.: Two weeks ago I saw a case of fecal passage from the bladder. Proctosigmoidoscopy effectively excluded the rectum and sigmoid as the site of the perforation. Definite pathologic changes and characteristic mucopus of amebiasis were seen, which directed laboratory examinations and proved the correctness of the clinical diagnosis. These examinations and the diagnosis would have been embarrassed by either a barium or a bismuth enema, both of which are parasitocidal and should never be used prior to proctosigmoidoscopy and microscopic examinations when there is an ulceration that might be parasitic. Later, a roentgen study was made and cystotomy was ordered, and at this time it was easy to palpate a cancer mass which involved the colon above instrumentation. Often small adenomas and ulcers are found which x-rays cannot reveal. The appearance of the intestinal mucosa is often a factor which x-rays cannot reveal. A careful observer of pathologic changes of the throat needs no less the x-rays in streptococcic or tuberculous or Vincent's infections of the throat and buccal mucosa than does one who observes the same pathologic changes in the intestine. These statements should in no wise minimize the importance of roentgen examinations, which should come in proper sequence. There are conditions in the colon and sigmoid which seem to be remote from an actual pathologic condition in the intestine at that point. I refer particularly to those conditions which are observed especially in the South, where pellagra and flagellosis are so prevalent; when there is not so marked a pathologic condition except in cases of mixed infections, x-rays would show a marked spasticity. No clinical assembly of physicians should be without a competent man to make proctosigmoidoscopic examinations, a competent pathologist, a competent bacteriologist and a competent protozoologist. There are less than a hundred men in this country who can properly diagnose by laboratory study the different protozoa in this country or can even classify the known pathogenic amebas.

Dr. Louis J. Hirschman, Detroit: I don't like the word "versus," in the title of this paper. There is no conflict or controversy between different diagnostic methods. They should go hand in hand. I agree with Dr. Yeomans that the sequence of diagnosis has been reversed. I, too, have seen patients with something wrong with the colonic or rectal function and yet the gastro-intestinal roentgenograms did not seem to show it. The proctologist made the diagnosis immediately. Why does one make a complicated roentgenologic study of anything that is in the range of one's eyesight or in the reach of one's examining fingers? Many pathologic entities in the lower bowel can be seen with the proctoscope and felt with the finger. Fluoroscopy should also be used. I don't believe in films alone. This is one time when a fluoroscope should be employed. Fluoroscopy enables one to see the changes in position and the different variations in physiologic or pathologic motion, with the roentgenologist who, after all, is a consultant. One should not be satisfied with positive conditions in the lower bowel, but after one has seen as far as one can see, and felt as far as one can feel, x-rays, barium enemas and manipulation should be used to make sure that there is nothing else higher up that will go undiscovered. I have had the experience of seeing a large polyp through the sigmoidoscope, but after following up with the x-rays I found, besides, a carcinoma of the median colon.

I have a case of carcinoma of the rectum and another of the sigmoid with an area of 4 inches of healthy bowel between. The sigmoidoscope alone should not be relied on. The time may come when there may be a floating camera that the patient can swallow, and under radio control, television will come into effect, and it can be stopped when one wishes as it goes on its peristaltic journey, by touching a button, and then have it pass out. Until that time comes, the x-rays will have to be depended on for examining parts of the alimentary canal that one cannot see.

Dr. Curtice Rosser, Dallas, Texas: Unquestionably, so far as proctologic opinion is concerned, the proper order of procedure is as described: *proctoscopy followed by roentgenoscopy* of the colon and, if no evidence of obstruction is found, by a gastro-intestinal series. As a matter of fact, this gives one, in addition to the favorable situation mentioned by Dr. Yeomans, a field clear of barium in the rectum for proctoscopy and a colonic picture unobscured by barium in the small bowel. There is a tendency in medical gatherings to discuss in detail exact methods of diagnostic procedures, overlooking the concrete fact with which we as proctologists and gastro-enterologists continue to be faced, that our real problem continues to lie not in determining how to make examinations but in our inability to obtain a patient to diagnose during earlier stages when treatment of any kind is efficacious. The bismuth and paregoric regimen continues to hold the diarrheic individual for three, to four, to six months before he gets to a gastro-enterologist. Bleeding cancers come from twelve to sixteen months after symptoms develop and the mortality has been more greatly increased by this fact than by any reversal of the proper order of examination.

Dr. Frank Smithies, Chicago: I presume it is occasionally necessary to have a perfectly obvious paper like this to check us on what we think we are doing right or what we think we are doing wrong. I always understood that the proper scheme of procedure was the examination of the fresh stool, the proctoscopic study and the gastro-intestinal series. I haven't heard many of the proctologists speak of the examination, and the frequent examination, of the freshly passed stool. They have relied largely on looking 30 cm. up and then "cussing out" the roentgenologist and the internist because they did not see anything; also they have had the idea that the internist had interfered with their own examination. I can't see how anybody could detect anything from x-rays like the ones that have been presented, even the x-ray man himself. If one is to do a roentgen examination, he must do it properly, with a progress meal; fluoroscopy, enema plate and the like. So far as proctoscopy is concerned, that, too, must be done properly. Dr. Jelks has said that there are not more than a hundred men in the country who can classify parasites. I could say there are not a hundred men in this country who can do a proctoscopic examination. Many times I see polyps, carcinomas and ulcers that have been missed, because a patient during proctoscopy is placed *on the right or left side, or put in a knee-chest position* on a table so high that all one can get is a glimpse of the internal sphincter. If proctoscopy is to be done, it must be done right, on a proper, special table, with proper air inflation, and with the patient in a position so that something may be seen if it is there. I had a proctologist recommend the removal of a section of bowel on account of a tumor. There was a tumor, but it was secondary to a mesothelioma of the left kidney. A proctologist should be an internist first and he should be perfectly familiar with his own line of examination, which all too frequently he is not. He should also realize that what he sees is not the whole story. Dr. Hirschman hinted at that. The proctologist should remember, particularly with regard to protozoic infestation, that when he gets, from a bit of mucus, active protozoa such as *Endameba,* the lesion is far advanced and he is not diagnosing an early protozoic infestation of the alimentary tract.

Dr. Max Einhorn, New York: I fully agree that no method of examination of the rectum should be omitted in making a diagnosis, and the simpler the examination, the better. If a mass can be felt with the finger in the rectum, a diagnosis can easily be made. The proctoscope can be used in addition, but there are conditions in which a diagnosis is impossible or difficult, even if every aid to diagnosis is used.

Dr. Descum C. McKenney, Buffalo: I wish to emphasize the importance of a position for sigmoidoscopic examination such as one gets with a Buie or Hanes table. The patient must be stood on his head, practically speaking. Another thing, in making all rectal examinations, the man who does it properly not only studies the lower end of the bowel but also takes into consideration the troubles farther up. Recently I saw two men, aged 36 and 71, respectively. Both had hemorrhoids so large that they acted as rubber rings to sit on and explained their bleeding. In the younger man I found a carcinoma at the upper end of the rectum. In the older man I found a tumor, an adenoma the size of a hen's egg, probably benign, at the lower end of the pelvic colon; unfortunately, I didn't get a chance to remove it or study it further, because he died of a stroke later. Both of these were easily diagnosed with the sigmoidoscope, whereas the x-rays would probably have missed them. There are a few things in making a sigmoidoscopic examination that are quite valuable. The length of the tube does not determine the field for examination, because if one studies the type of secretion that comes down from above the end of the instrument, one will get some valuable hints as to what may be going on higher up. A rectal tube or a catheter attached to a bulb or other suction apparatus can be put through the sigmoidoscope *when it reaches its highest point, and with it one can often* collect secretions that are valuable for examination. To overcome one difficulty in the passage of the sigmoidoscope, the physician can often, with the instrument in place, leave the patient in position while he answers the telephone or sees another patient, and when he comes back the spasm will have been relieved and the sigmoidoscope will usually pass on easily another two or three inches. Another thing that sometimes helps me to pass the instrument farther is the use of saturated solution of magnesium sulphate on a swab. I think that Dr. Beach of Pittsburgh told about that for the first time.

Dr. Anthony Bassler, New York: As I get the point of Dr. Yeomans' paper, he wants to present the value of the sigmoidoscopic examination. It is an interesting thing that for many years the proctologists have been pounding on that one idea, and yet there seems to be a gap in the universal use of the sigmoidoscopic for which there is really no excuse on the part of any one, however limited his practice may be. Physicians ought to make their examinations complete, and there is no doubt that the use of this instrument is valuable in clinical work. A criticism that I have of the proctologist is that the use of the instrument is always centered around pathologic changes of carcinoma, adenoma and hemorrhoids, and things of the sort that have somewhat of a surgical interest. I want to step down into their domain for a minute and say this: The use of the proctoscope from a gastro-enterologic standpoint has a most valuable application. Familiarity with the appearance of the mucosa can commonly suggest parasitic infections; appearance of ulcers commonly suggests types of biologic infections, and one has a means of seeing an ulcerated colitis by eye. Chronic infections of the intestine have *commonly a certain* characteristic appearing mucous membrane. There is the typical atrophic mucous membrane and the hypertrophic forms which are secondary to certain classic types of intestinal toxemias. I am not speaking on surgical matters of proctology but on clinical matters of gastro-enterology, and I would substantiate the proctologist's effort and try to popularize the use of this instrument as a clinician and not as a proctologist or surgeon. Nobody should miss the valuable clinical opportunities that come in the use of this endoscopic instrument in even straight medical gastro-enterology.

Dr. Frank C. Yeomans, New York: This paper is not on the technic of sigmoidoscopy. The title was selected to draw attention to the subject rather than to cause a discussion of the relative merits of proctoscopic and roentgen examinations. The two are complementary and essential in many instances. Every physician understands the importance of the stool examination. Reports of routine examination are frequently received "negative for ova and parasites" or "occult blood," which mean nothing, and I found it necessary to get the material fresh from the mucosa, either on the eye of the rectal tube or by scraping, which is much better, in cases of dysentery. This is not a paper for the specialist. Its purpose is to focus attention on a glaring defect in general practice. The great majority of general practitioners do not own x-ray machines or proctoscopes and they are not familiar with their use. Too often and quite as a routine the physician sends his patient to the roentgenologist without his having a proctoscopic or digital examination. I have many consultations in hospitals and frequently am told that a proctoscopy has been done, usually by the junior intern, who notes that he thinks the mucous membrane is inflamed or swollen in some spot. The bowel may not have been properly emptied. One cannot blame the intern for not knowing what a normal bowel looks like. He never saw one in medical school and has forgotten most of the living pathologic condition of the That is the point I am emphasizing. It is a practical point for bowel. That happens in the metropolis and I am sure it happens, only to a greater degree, in the rural parts of the United States. the welfare of the patient and for the credit of the profession.

TREATMENT OF INTERMITTENT CLAUDICATION WITH HYPERPYREXIA PRODUCED BY BATHS *

H. G. MEHRTENS, M.D.
AND
P. S. POUPPIRT, M.D.
SAN FRANCISCO

In the routine treatment of 500 neuropsychiatric patients with hyperpyrexia produced by baths, it became apparent that certain types of pain were especially amenable to such therapy. In this favorable group were cases with vascular lesions and vasoneuroses. The symptoms complained of ranged from the more trivial discomforts on vigorous exercise to crippling incapacity on any exertion. In the early and less typical cases a definite classification was doubtful. In severe cases the diagnosis was obvious, but all cases could be included under the symptom complex of intermittent claudication.

Intermittent claudication is a term now rarely considered as descriptive of a clinical entity. It should be restricted to a combination of symptoms observable in a number of pathologic conditions. While such a symptom complex may result from many forms of arterial lesions, two varieties, arteriosclerosis and endarteritis obliterans, will include far the larger proportion of cases. Hunt[1] has emphasized that the two chief factors, angiosclerosis and angioneurosis, are usually combined. The distribution of the lesions allows of a most varied clinical picture, including spinal, cerebral, mesenteric, retinal and lumbar types.

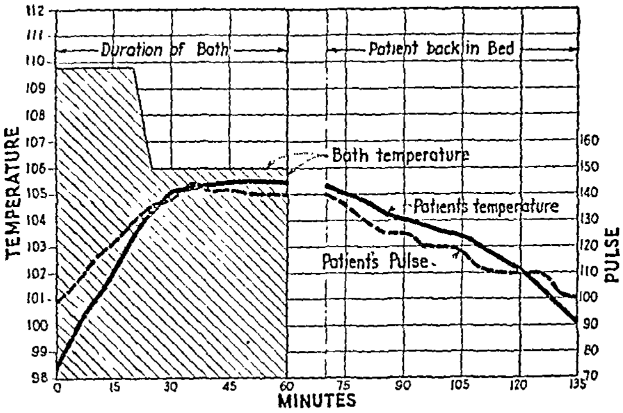

Chart 1.—*Hyperpyrexia produced by baths.*

In the past many methods have been employed in the treatment of intermittent claudication, including immersion of the extremities in hot water, use of diathermy locally, protein shock,[2] intravenous injections of hypertonic sodium chloride,[3] and two surgical methods—that of stripping the peripheral vessels[4] and that of removing the sympathetic ganglions.[5] Intravenous sodium chloride solution has been reported as symptomatically helpful. Protein shock is temporarily of benefit and indicates the results that may be anticipated from surgery. The surgical methods, particularly ganglionectomy, apparently give the most satisfactory results when applied in carefully selected cases.

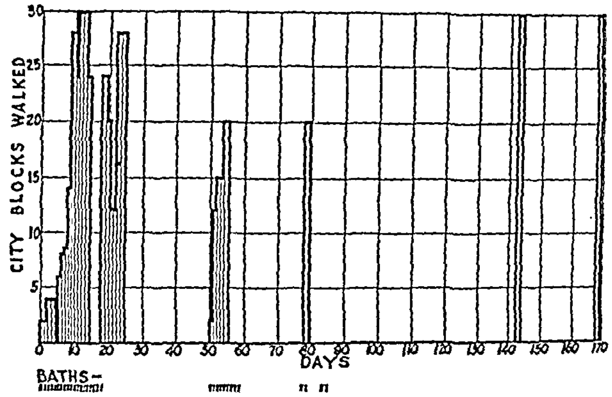

Chart 2.—*Effect of baths on ability to walk, in a case of arteriosclerosis.*

TECHNIC OF THE BATH

An ordinary bathtub and bath thermometer may be used, although the continuous tub admits of a more satisfactory control of fever. An ordinary mouth thermometer will suffice at lower temperatures, but a rectal thermocouple is very helpful at high temperatures or for noncooperative patients. For this type of patient a mouth temperature of from 103 to 105 F. is sufficient.

Our technic consisted in immersing the patient in a bath at 110 F. With timid patients, or on the occasion of the first bath, the temperature can be started at 105 F. Ordinarily 110 F. was maintained until the temperature of the patient reached a point within 1½ degrees of the fever desired. Then the temperature of the water was reduced until it corresponded with the mouth temperature of the patient. The routine bath lasts one hour, but when indicated it is feasible to maintain the patient's temperature by wrapping him in blankets. A daily bath repeated fourteen times is indicated for most patients, although twice this number were given consecutively with no added difficulty (chart 1).

CLINICAL RESULTS

In the great majority of the less severe cases, symptoms were ameliorated by a series of fourteen baths. In more than 30 per cent no recurrence took place during the period of observation. In the severe cases the results were varied. When gangrene had set in, no improvement was obtained even when the fever was produced without wetting the gangrenous tissues. In six cases in which gangrene had not appeared but symptoms were severe, every patient received symptomatic relief lasting from one week to a year. Every patient gained weight during the course of baths, although the immediate loss of weight following a bath ranged from 3 to 5 pounds.

Following is the report of a case of arteriosclerosis:

A Jewish Hungarian carpenter, aged 54, entered the hospital complaining of pain in the calves of both legs produced by walking half a block which disappeared with rest. This condition had been present for eight months and was increasing in intensity in spite of numerous courses of diathermy. Examination showed a residual hemiplegia, sclerotic radial arteries, feet pale and cold with absent dorsalis pedis and posterior tibial pulsations of both sides. Roentgenograms showed calcification of arteries of the legs. The diagnosis was arteriosclerosis.

The patient was given a series of hyperpyrexia baths with resulting improvement beginning after the second bath and gradually increasing, as shown in chart 2, until, after eighteen daily baths, he was able to walk thirty city blocks without discomfort. Twenty-five days after dismissal he reentered because of a return of slight pain in the legs on walking two blocks. He was given six daily baths, following which he was able to walk twenty blocks. Twenty-five days later he returned for one prophylactic bath. At that time he could walk twenty blocks without pain. He has been under observation for a year, has had no relapses, no further treatment has been given, and he is now walking from 3 to 5 miles without pain. In spite of the good clinical results, no actual change could be demonstrated in the vessels.

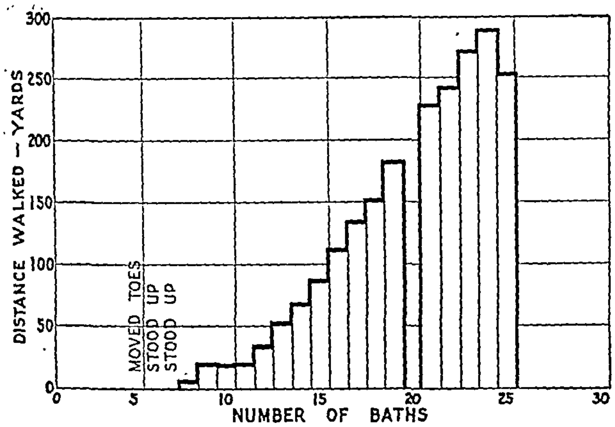

Chart 3.—Effect of baths on ability to walk, in a case of endarteritis obliterans.

Chart 3 represents the progress made by a patient with endarteritis obliterans who showed symptoms of intermittent claudication. The improvement in this case did not begin until the seventh day and was of no consequence until the eleventh day, following which a steady gain was made until the patient could walk 250 yards without pain.

It is interesting to speculate as to how the hyperpyrexia does its work. George Brown[6] concludes that the collateral circulation in thrombo-angiitis obliterans is in a spastic state from which it is released by foreign protein reaction. The fever resulting from the baths may act in a similar manner. There remains the possibility that hyperpyrexia acts centrally on the vasodilator center, accounting for a more prolonged increase in circulation than an hour's fever with its resultant peripheral dilatation would explain.

COMPLICATIONS OF HYPERPYREXIAL BATH THERAPY

In a series of 5,000 treatments of patients varying in age from 16 to 87, including ones with myocarditis, hypertension and severe degrees of marasmus, no fatalities occurred. Complications were avoided by individualizing the treatment and by constant supervision of the patients.

INDICATIONS

Hyperpyrexia baths, because of their safety and simplicity of administration, have a field of usefulness in early cases of vascular disease with symptoms of intermittent claudication. Even in the more severe cases this therapy may find a place because sympathetic ganglionectomy, as well as the use of intravenous hypertonic saline solution, is recommended chiefly in selected cases of Buerger's disease. Arteriosclerosis with calcification is infrequently benefited by the foregoing procedures, but hyperpyrexia has in our experience proved worthy of trial.

CONCLUSIONS

1. Hyperpyrexia produced by baths is a useful therapeutic measure in the symptom complex of intermittent claudication.
2. The milder cases offer the better chances of improvement.
3. Cases in which gangrene has already taken place show no amelioration.
4. Arteriosclerosis with calcification in the peripheral vessels presents a favorable field for this therapy.

Stanford University Hospital—2361 Clay Street.

Clinical Notes, Suggestions and New Instruments

SHALL SYRINGOMYELIA BE ADDED TO THE LESIONS APPROPRIATE FOR SURGICAL INTERVENTION?

Charles H. Frazier, M.D., Sc.D., Philadelphia

By a recent experience my attention has been called to benefits that may be derived in syringomyelia from surgical intervention. Looking over the literature I was surprised to find no references of American authorship to resort to operation for this condition. As a matter of fact, the first recorded operation for syringomyelia is contained in an article by Puussepp,[1] who related his operative experience in two cases. Only four other pertinent articles have appeared since Puussepp's original contribution; one by the same author,[2] one by Förster,[3] one by Schmieden,[4] and one by Oppel.[5] I shall not review these articles in detail. *Suffice it to say that Puussepp has operated on four patients* with manifest improvement; Schmieden on one patient with definite improvement in movement of arm and leg and of sensation; Oppel performed seven operations on six patients with results varying from negative to brilliant. Up to the present time, therefore, including my own there are only twelve cases on record of the surgical treatment of syringomyelia.

REPORT OF CASE

History.—R. S., a woman, aged 35, referred to the Neurosurgical Service of the University Hospital by Dr. Walter Timme, noticed a sense of tingling in the entire left upper extremity, fifteen years before, immediately after sneezing, which continued for a month, and following this there developed weakness in the left forearm and left ankle. Associated with this was pain in the left ankle and left thigh. The weakness in the left upper and lower extremities gradually increased and eleven years ago (1919) weakness in the right arm was noticed. Ten years ago (1920) there was a gradual weakness and loss of motion in the right upper extremity and four months later sensation in the right upper and lower extremity was almost completely lost. During the past years she developed clonic spasm of the right shoulder and muscles of the throat and quite recently incontinence.

Examination.—There was no voluntary movement of the left upper extremity. In the left lower extremity voluntary motion was greatly impaired and sufficient only to make a few steps possible with help. There was restricted movement of the right elbow joint, and the fingers of the right hand were rigidly flexed. The movements of the right lower extremity were only slightly impaired. The sensory changes were profound. Sensation of all forms was lost in the back of the head, trunk, both upper extremities and the right lower extremity. In the left lower extremity sensation for touch, pain and temperature was partially preserved. In the face, tactile sensation was acute on both sides but there was impairment of temperature and pain sensation—a condition typical of syringomyelia.

There was bilateral atrophy and fibrillary tremor of the tongue.

There was a coarse nystagmus on looking to the right, rotary on looking to the left, lateral on looking upward and downward.

The patellar and Achilles tendon reflexes were increased on the right and diminished on the left. There was abortive ankle clonus and Babinski reflex.

By the manometric test there was no evidence of a spinal block.

April 14, 1930, laminectomy was performed under colonic ether anesthesia. The laminae and spinous processes of the seventh cervical and first thoracic ribs were removed. The spinal canal at this level seemed abnormally wide. When the dura was incised, an abundance of cerebrospinal fluid could be seen in the subarachnoid space.

The cord was pulsating and was affected by respiration. As I was observing the cord and before the incision was made the cord collapsed. How the fluid escaped I could not determine.

In deciding on a point at which to make the incision in the cord, I selected an avascular space just to the right of the median line. The wall of the cyst at this level was but from 2 to 4 mm. thick. After the incision was made, a thin strip of the finest gutta percha tissue was inserted into the cyst to insure permanent drainage.

After securing hemostasis the dural incision was closed with a continuous silk suture and the muscles with interrupted silk sutures.

The immediate convalescence was unusually free from discomforts. The wound healed by first intention and the patient was discharged, April 28, two weeks after the operation.

As to the immediate effects, the incontinence was immediately relieved. The spasticity of the fingers of the left hand had subsided so that passive movement was possible, a condition not possible before the operation. The patient could extend the fingers of the right hand. This she could not do before. The head was held erect and not tilted to one side. Especially did the patient feel a sense of relaxation, and the sense of tension had in large measure subsided.

Sensation for touch and temperature was restored in the zone supplied by the second and third cervical nerves and in the trigeminal distribution; sensation for pain and temperature was completely restored on the right side of the forehead and only slightly impaired elsewhere.

The improvement that followed was definite; that it was not more striking must be attributed to the duration and extent of the lesion. The cessation of incontinence more than justified the undertaking. Not only had the patient's condition improved in these various particulars but the improvement in her morale, of itself, was sufficient, it seemed to me, to justify the operation.

On the results obtained in the series of cases reported, no one should question the propriety of surgical intervention. As a matter of fact, the underlying principle—the relief of pressure—is the same as that on which many operations on the brain and spinal cord are based. In my case, for instance, the development of urinary incontinence was a manifestation of pressure. Perhaps it is too early to predict the end-results. Oppel thinks it is at least reasonable to assume that the incisional openings into the cyst will not close, but to insure permanent drainage I inserted a narrow strip of thin gutta percha tissue into the cavity and I learned later that Oppel had used a strip of dura for the same purpose. Space does not permit a discussion of the technic in detail. Suffice it to say that in most instances the lower segments of the cervical cord should be exposed and an incision made of sufficient length to establish drainage and prevent reaccumulation of fluid in the cavity. The only question in dispute is the site of the incision. Poussepp advises an incision from 2 to 4 mm. long to one or the other side of the median line, the right or the left side being chosen according to whether the symptoms are more advanced on one side or on the other.

Altogether, this initial experience with the surgery of syringomyelia was more than pleasing and from my own experience and that of others I should not hesitate in advising intervention, and at as early a stage of the disease as possible.

133 South Thirty-Sixth Street.

PELLAGRA-LIKE SKIN LESIONS APPEARING IN THE COURSE OF A KETOGENIC DIET *

Riley H. Guthrie, M.D., Palmer, Mass.

The case here reported illustrates a relatively new complication—a dietary deficiency syndrome—due to poorly supervised ketogenic diet.

B. R., a woman, aged 20, single, the only child of living and healthy parents, was reared in comfortable circumstances. Her early development was uneventful except for whooping cough at 1½ years, and measles at 8 years. There was nothing relevant in the family history. Nocturnal convulsions were first observed at 14. Various methods of treatment were tried in her case. At 16 she was given glandular therapy in the form of whole gland pituitary substance and thyroid extract because her basal metabolic rate was — 24 per cent and she was slightly overweight. At that time she presented some vaguely described neurologic signs; i. e., some cranial nerve involvement and positive Babinski reflex on the left. About this time her tonsils were removed. The convulsions gradually became more frequent, both nocturnal and diurnal. After physical therapy and electrotherapy failed she was placed on phenobarbital. She did not respond well to phenobarbital therapy, and the dosage was increased to 4 grains (0.26 Gm.) a day. In January, 1930, at the age of 19, she was placed on a ketogenic diet with a very low protein, relatively liberal carbohydrate and high fat content. This diet was carried out in her home without proper medical supervision. For a time convulsions decreased in number but finally returned with such frequency that phenobarbital was again increased to 4½ grains (2.9 Gm.) daily. She had been refractory to all forms of treatment. After seven months of this ketogenic diet she developed an erythema on the dorsal surfaces of her hands and wrists, and about her neck. One observation was made in the outpatient clinic of the Monson State Hospital, Aug. 21, 1930. Her mother stated that the ketogenic diet had been discontinued three weeks previously because the patient was growing worse and mental deterioration was progressing. The erythema referred to previously had become less marked after her dietary restrictions had been removed.

A dusky desquamation of glovelike distribution was present over the dorsum of her hands and wrists. A similarly pigmented desquamation was about her neck, of collar-like distribution. There was a tawny pigmentation over the dorsal aspects of both feet and external malleoli. The following neurologic summary was made by Dr. Paul I. Yakovlev: The patient was fairly well nourished. She was inactive, sluggish and indifferent. Her comprehension was impaired and she answered questions slowly, carelessly and in monosyllables. Her speech was slurring, her body attitude atonic and her movements hesitating. Her station was unsteady. Her arms hung flaccidly, and her gait was slouchy. There was nystagmus on lateral gaze. Diadokokinesis was clumsy and slow, and there was marked hypermetria in heel-to-knee tests on both sides. The patellar reflexes were equal and pendulous (atonic). The tonic postural reflexes were weak or abolished. The plantar reflexes were normal. The abdominal reflexes could not be elicited. Ophthalmoscopic examination was negative.

---

* From the Monson State Hospital.

COMMENT

The neurologic signs—generalized muscular atony, clumsy diadokokinesis, absent abdominal reflexes, nystagmus and positive Romberg—might be accounted for by the prolonged use of large doses of phenobarbital. The prolonged sedation and resultant vegetative existence of this patient might easily influence her nutritional status and, therefore, play a part in the causation of her pellagra-like skin symptoms. However, the history of a very low protein diet led up to the appearance of this well known protein deficiency syndrome, and the skin symptoms began to subside as soon as dietary restrictions were removed.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

W. A. PUCKNER, Secretary.

ANTIRABIC VACCINE (See New and Nonofficial Remedies, 1930, p. 352).

Medical Arts Laboratory, Inc., Oklahoma City, Okla.

Antirabic Vaccine, Semple Method.—An antirabic vaccine prepared according to the general method of David Semple (phenol killed). It consists of a sterile suspension, in distilled water, of the brain and cord substance of rabbits moribund from the injection of fixed virus rabies. The virus is killed by the use of phenol and by incubation at 37 C. for forty-eight hours. The finished product contains 0.5 per cent of phenol. Marketed in packages of fourteen vials, each containing 2 cc.; in packages of fourteen vials each containing 2 cc. and a syringe; in packages of fourteen syringes, each containing 2 cc. All of the doses are of the same potency; one dose is to be given daily over a period of fourteen days. In severe cases, two doses are given daily for several days.

DIPHTHERIA TOXOID (See New and Nonofficial Remedies, 1930, p. 364).

E. R. Squibb & Sons, New York.

Diphtheria Toxoid-Squibb (see New and Nonofficial Remedies, 1930, p. 366).—Also marketed in packages of twenty 1 cc. ampules of diphtheria toxoid and two 1 cc. ampules of diluted diphtheria toxoid for the reaction test.

NORMAL HORSE SERUM (See New and Nonofficial Remedies, 1930, p. 340).

E. R. Squibb & Sons, New York.

Normal Horse Serum (see New and Nonofficial Remedies, 1930, p. 341). —Also marketed in packages of one 50 cc. vial.

SODIUM GOLD THIOSULPHATE.—Sodii et Aurii Thiosulphas.—Gold Sodium Thiosulphate.—Sodium Aurothiosulphate, $Na_3Au(S_2O_3)_2.2H_2O$. The complex salt formed from 1 molecule of gold thiosulphate and 3 molecules of sodium thiosulphate. It contains approximately 37.4 per cent of gold.

Actions and Uses.—A review of the literature in regard to the use of gold and sodium thiosulphate in the treatment of lupus erythematosus reveals in general quite satisfactory clinical results, and it is considered a distinct advance in the therapy of this condition. Although there have been many recurrences in cases originally thought cured, nevertheless the beneficial and often curative action of the drug in a good percentage of the cases seems to warrant giving it a definite place in the treatment of a disease for which at present there is no specific remedy.

Gold and sodium thiosulphate must, however, be used with extreme caution. Dosages at first advocated have been found to be too great, resulting frequently in severe reactions, sometimes resulting fatally. Even with much smaller doses, accidents of this kind have occurred. The reactions most commonly encountered are varying degrees of fever, diarrhea, vomiting, albuminuria, enteritis, stomatitis, prostration and shock. Skin reactions consist of varying degrees of erythema, urticaria, severe papular and vesicular dermatitis, and scarlatiniform and exfoliative dermatitis. Published necropsy reports reveal conditions usually found in metal poisoning.

Dosage.—At present the initial dose preferred is from 0.01 to 0.025 Gm. (⅙ to ⅜ grain) intravenously given in from 2 to 5 cc. of sterile distilled water. Subsequent doses given at weekly intervals are increased 0.01 Gm. (⅓ grain) per dose, not exceeding a maximum of 0.075 Gm. (1⅙ grains) for women and 0.1 Gm. (1½ grains) for men, provided no reactions have occurred. The drug may be continued cautiously in smaller dosage following complete recovery from mild reactions but should be discontinued permanently if severe reactions have occurred. A careful physical examination to rule out disease of the liver and kidneys, or other serious organic disorders, should be made before using this therapy. Cases of lupus erythematosus of the disseminated type are most likely to show an extreme idiosyncrasy for the drug, and if used at all in such cases it must be given in very small doses not exceeding 0.005 Gm. at the start and cautiously increased to a maximum of probably not over 0.025 Gm.

Sodium gold thiosulphate occurs in white, glistening, needle-like or prismatic crystals. The aqueous solution is colorless. It is freely soluble in water; very slightly soluble in alcohol, ether and chloroform. An aqueous solution (1: 200) is neutral or faintly alkaline to litmus.

Sodium gold thiosulphate decomposes without melting when heated gently, leaving a brown residue on ignition. An aqueous solution (1: 200) assumes a yellow color on standing and decomposes.

Dissolve 0.1 Gm. of sodium gold thiosulphate in 20 cc. of water: separate portions of 2 cc. each yield a brick red precipitate with 0.4 cc. of silver nitrate solution; a purple red color followed by a gray brown precipitate on addition of 0.2 cc. of ammonia water and 0.5 cc. of solution of hydrogen peroxide, followed by heating to boiling point (*distinction from arsenic, antimony and tin*); no precipitate with 0.3 cc. of sodium iodide (15 per cent); a bluish purple (purplish gold) precipitate preceded by disappearance of the iodine color with 0.3 cc. of iodine test solution (*presence of* $S_2O_3^{--}$); no precipitate in the cold, on addition of 0.5 cc. of concentrated hydrochloric acid, but on heating to boiling a precipitate then forms; a precipitate with 0.5 cc. nitric acid; no precipitate on addition of 0.2 cc. barium chloride solution and 0.2 cc. diluted hydrochloric acid (*sulphate*); no apparent change in cold or after heating with 0.4 cc. of sodium bisulphite solution (*no auric compounds*).

Dissolve about 0.5 Gm. of sodium gold thiosulphate, accurately weighed, in 5 cc. water, carefully add 4-5 cc. nitric acid and 25 cc. water; agitate; when the reaction has subsided, filter the residue on to a tared Gooch crucible. Wash the residue with six 25 cc. portions of water and save the filtrate for determination of sulphur constituent. Wash the residue in crucible with alcohol and ether after removal of the filtrate; dry the contents at 100 C. and ignite to constant weight. The weight of gold should not be less than 37.0 per cent nor more than 37.5 per cent.

Transfer the filtrate from the gold precipitation to a 250 cc. volumetric flask and make up to volume by addition of water. Pipet 50 cc. of the solution to a 500 cc. beaker, add 5 cc. hydrochloric acid, evaporate to one-third volume, dilute to 250 cc., heat almost to boiling temperature, slowly add with stirring 10 cc. of hot barium chloride solution, digest, filter through tared Gooch crucible, dry and ignite the residue to constant weight. The weight of barium sulphate corresponds to not less than 24.2 per cent nor more than 24.7 per cent of sulphur.

Gold Sodium Thiosulphate-Abbott.—A brand of sodium gold thiosulphate-N. N. R.

Manufactured by the Abbott Laboratories, North Chicago, Ill. No U. S. patent or trademark.

Ampules Gold Sodium Thiosulphate-Abbott, 0.05 Gm.
Ampules Gold Sodium Thiosulphate-Abbott, 0.1 Gm.
Ampules Gold Sodium Thiosulphate-Abbott, 0.25 Gm.
Ampules Gold Sodium Thiosulphate-Abbott, 0.5 Gm.

DIPHTHERIA TOXIN-ANTITOXIN MIXTURE (See New and Nonofficial Remedies, 1930, p. 356).

The National Drug Co., Philadelphia.

Diphtheria Toxin-Antitoxin Mixture (Diphtheria Prophylactic) (See New and Nonofficial Remedies, 1930, p. 357).—Also marketed in packages of one hundred and fifty 1 cc. vials, fifty immunizations.

DIPHTHERIA TOXOID (See New and Nonofficial Remedies, 1930, p. 364.

The National Drug Co., Philadelphia.

Diphtheria Toxoid (See New and Nonofficial Remedies, 1930, p. 365).—Also marketed in packages of five immunization treatments, consisting of fifteen vials, each containing one human dose; in packages of fifty immunization treatments, consisting of 150 vials, each containing one human dose. For the two dose method of treatment the following forms are marketed: in packages of one immunization treatment, consisting of two vials, each containing one human dose; in packages of five immunization treatments, consisting of ten vials, each containing one human dose; in packages of ten immunization treatments, consisting of one vial containing twenty human doses; in packages of fifteen immunization treatments, consisting of one vial containing thirty human doses; in packages of fifteen immunization treatments, consisting of thirty vials, each containing one human dose; in packages of fifty immunization treatments, consisting of one hundred vials, each containing one human dose.

POLLEN ALLERGEN SOLUTIONS-SQUIBB (See New and Nonofficial Remedies, 1930, p. 27).

The following pollen allergen solutions-Squibb are marketed in treatment set packages of three 3 cc. vials, the first containing 0.0005 mg. of nitrogen per cubic centimeter, the second containing 0.008 mg. of nitrogen per cubic centimeter, and the third containing 0.05 mg. of nitrogen per cubic centimeter.

Ragweed Combined Pollen Allergen Solution-Squibb; Timothy Pollen Allergen Solution-Squibb.

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

535 North Dearborn Street - - - Chicago, Ill.

Cable Address - - - - "Medic, Chicago"

Subscription price - - - - - Seven dollars per annum in advance

Please send in promptly notice of change of address, giving both old and new; always state whether the change is temporary or permanent. Such notice should mention all journals received from this office. Important information regarding contributions will be found on second advertising page following reading matter.

SATURDAY, DECEMBER 20, 1930

DUES FOR 1931

Among the pages of The Journal this week will be found a colored slip of irregular shape. This slip serves a double purpose. It is a reminder or statement for 1931 Fellowship and subscription dues which are now payable. When properly folded the slip is also a perfect envelop which needs no addressing or postage. The check, draft or money order may simply be enclosed in this envelop, dropped in the mail, and the matter of 1931 dues is disposed of in about one minute's time. It is earnestly urged that every Fellow and subscriber act promptly on this reminder. The colored slip also lists the various special journals published by the Association, as well as *Hygeia*. This is an added convenience, as all subscriptions may thus be covered with one remittance. Full directions for folding the envelop appear on advertising page 12.

SERUM PROTEIN AND EDEMA

There can no longer be any doubt of the close interrelationship between the occurrence of an abnormally low content of protein in the blood serum and the possible development of edema. The latter phenomenon may become manifest under a variety of pathologic conditions, notably when certain types of cardiovascular disorders arise and they are attended with renal disorder. The studies of recent years have demonstrated, however, that generalized edema may occur in the absence of detectable primary disease in the cardiovascular and renal systems. An illustration is afforded by the so-called malnutritional edema. This was prevalent during and just after the World War in central Europe, where people were forced to subsist largely on turnips and other root vegetables for long periods. Schittenhelm and Schlecht[1] studied the condition in prison camps and decided that rest and increased protein and fat in the diet relieved the edema. They estimated serum proteins by refractometer methods and found that refractometric indexes were low in 50 per cent of the cases. Finally, the disease was attributed to a lack of protein and possibly of fat in the diet. The symptoms were not those of a lack of vitamins.

Edematous conditions have been produced experimentally in animals by prolonged feeding of diets poor in protein.[2] Leiter[3] lowered the serum proteins by plasmapheresis. He bled animals, centrifugated off the plasma, mixed the cells with physiologic solution of sodium chloride, and replaced them in the animals. By this means the serum proteins were lowered and an edema developed. Others have succeeded similarly.

The relationship between serum proteins and the occurrence of edema in man has lately been stressed with especial reference to the therapeutic management of the condition by increments of protein in the dietary intake. In a series of patients at the Yale School of Medicine, Peters and his co-workers,[4] for example, observed that edema usually is present when the serum proteins are below 4 per cent, and never when they exceed 5 per cent. This condition obtains in so-called nephrosis. A case carefully investigated by Cowie and his collaborators[5] at the University of Michigan substantiates anew that there is a definite relationship between the serum protein and edema in childhood. Edema and ascites could be induced at will by feeding an amount of protein inadequate for the patient's nutritional needs, and likewise edema and ascites could be caused to disappear by feeding an adequate amount of protein. The amount of protein necessary to overcome and prevent edema was the amount that would bring the patient into a positive nitrogen balance of from 1 to 3.7 Gm. and the blood proteins up to 5 Gm. per hundred cubic centimeters. A continuous nitrogen balance of from + 2 to + 5 Gm. was incompatible with edema. The feeding of protein in this amount was unattended by an increase in the nitrogen content of the circulating blood or the retained fluids of the body. The retained nitrogen must therefore have been stored in some of the tissues. To secure the positive balances, an intake of 2.6 Gm. of protein per kilogram of body weight (1.2 Gm. per pound) was requisite. This is considerably more than Parsons[6] has recently found requisite for maintenance of a positive nitrogen balance in healthy children of the preschool group; i. e., from 4 to 8 years of age. Thus the protein factor in nutrition must be reckoned with in a way quite unlike that formerly considered universally desirable when albuminuria occurs.

DIET AND DENTAL CARIES

The conviction that defective teeth frequently act as foci of infection has served to stimulate further increasing interest in the care of the teeth, and attention is being centered with renewed vigor on the etiology of caries. The disease has long been known; paleopathologic studies of ancient Egyptian skulls bear evidence to its prevalence among the earliest races.[1] Dental caries is far more common among the more highly civilized races than among peoples living under less favorable or, at least, simpler conditions. However, there is no evidence for believing that caries is an endemic disease or that it is contagious. That general health has a bearing on the appearance of caries is shown by the fact that this disorder frequently is observed after periods of sickness and especially during pregnancy. In view of the many attempts to account for development of dental caries on the basis of either experimental or clinical conditions, the present state of our knowledge of the etiology of this disease is not gratifying.

The anatomic situation of the teeth renders an adequate study of dental pathology extremely difficult. Composed in large part of inorganic material, protected with hard enamel, the teeth are apparently chemically inert. Yet it is asserted that caries consists essentially of localized areas of solution of the mineral salts of the tooth. Furthermore, the fact that the teeth are in a moist, nonsterile chamber, subjected to wide ranges of temperature, to atmospheric gases and to contact with various food materials, renders experimental control in vivo a remote possibility. Little wonder, therefore, that caries has been variously attributed to such widely different agents as bacterial activity, the reaction and altered composition of the saliva, the influence of the secretions of the endocrine glands, and to faulty diet.

It is generally accepted that age is a factor in the susceptibility to dental caries, the incidence being highest between the ages of 7 and 20. For this reason it would appear to be particularly important to secure data on the factors influencing the appearance of this disorder in the young, with a view to developing effective prophylactic measures. This is the thesis on which are based recent extensive studies of Bunting, Hadley, Jay and Hard.[2] In a preliminary survey it had been observed that the prevalence of caries was much less among children given diets that would be generally regarded as adequate. In the main investigation the relative influence of antiseptic mouth washes, diet and a combination of these was studied. Five groups of children consisting of from 74 to 159 individuals were examined both before and after approximately a year had elapsed during which time the experimental measures were in effect. Four of the groups lived in state-supported institutions and so might be expected to have been under more or less satisfactory control.

The first two groups were provided with a satisfactory diet from which sugar was eliminated, except as it was used to make the food palatable. In this diet milk, green vegetables and fruit were prominent. In addition to this favorable diet, an antiseptic mouth wash was used daily. At the end of the period of observation, caries was active in 5 per cent and 6 per cent respectively of the children, while 80 per cent and 79 per cent respectively were free from the disorder. In the third group, attending a public school, mouth antisepsis was practiced, but control of the diet was not attempted. After nine months, 50 per cent showed active caries and only 25 per cent were free. The fourth group consisted of children in a state public school and was provided with an "unusually good" though not ideal diet. Here the mouth wash was omitted, and after a year, 75 per cent were normal while only 6 per cent showed active caries. In the fifth group, in which the ration was not carefully balanced, neither dietary change nor preventive treatment was carried out. Eighteen per cent of these children were free from lesions, while 49 per cent showed active caries.

In spite of the fact that studies of large groups of human beings inevitably suffer the drawbacks of noncooperation and lack of suitable controls, the investigation of Bunting and his co-workers is impressive. In the three groups in which milk, fruits and green vegetables were prominent in an otherwise well balanced diet, the progress of caries was either greatly diminished or prevented entirely, and this result was obtained whether antiseptic mouth washes were used or not. It was also pointed out that these children were in excellent general health at the termination of the investigation. In those groups consuming diets not entirely satisfactory according to modern nutritional standards, the disorder was active and its rapid course was not arrested. Among these children, likewise, the use of oral antisepsis exerted little influence.

While the observations here discussed have demonstrated little that is new concerning the immediate cause of dental caries, they do emphasize again the importance of diet in the control or prevention of the disease. At first glance the beneficial effect of the better rations might be attributed to a metabolic change, in which case one is confronted with the difficulty of explaining a situation in which an apparently inert and inactive structure such as the enamel is so altered chemically that it is rendered in a comparatively short time either more resistant or more susceptible to the effects of substances in the mouth. The other point of view emphasizes the mechanical action of foods such as greens and raw fruits which have been demonstrated to be of value in the prophylaxis and prevention of caries. Regardless of the point of view from which the beneficial effect of adequate diet is considered, it is satisfactory to know that this prevalent disease of childhood and youth can be largely controlled by a procedure at once physiologic and highly beneficial for many other reasons.

THE EFFECTS OF CONTINUED ADMINISTRATION OF IODIDE

Recently several experimental studies, carried out in different parts of the world, have indicated possible general benefits or detriments from administering iodide during long periods. The advent of iodide medication of whole populations, as with iodized table salt, iodized drinking water and iodized confections, has given special interest to these observations. So far as detrimental effects are concerned, there appears to be no doubt from these experimental studies that harmful effects in healthy animals receiving continued small doses have not been demonstrated. However, as to possible benefits, opinions and conclusions are not unanimous.

Favorable results indicating moderate though variable increases in body weight and growth of a great majority of white rats receiving iodized food continually during the major part of their lives have been mentioned previously in these columns.[1] The feeding of other salts to companion rats under the same conditions failed to exert similar benefits. These results with iodide agreed and correlated with a number of other beneficial effects on other functions in different animals observed in different parts of the world. For instance, growth of body weight of pigs, of sucklings of iodized mothers, and of rats on iodized milk was increased, the milk secretion of cows on iodized feed was improved in quality and quantity, iodized rats grew more rapidly, with more rapid sexual development, and iodized yeast showed more growth.

Now, however, two reports have appeared in this country which appear to deny the beneficial effects of iodide on growth and body weight. From the results of a limited study, Mendel and Vickery,[2] who used four groups of white rats, of which two groups were fed the usual complete artificial diet containing a trace of iodide and two groups were given 1.107 mg. of potassium iodide on yeast tablets daily with the same diet, venture the following opinion: "The variations between the records of individual animals are not inconsiderable, but the graphs that represent the averaged rates of gain for the respective groups are, we think, too nearly alike to permit claims of superiority for either type of diet." However, the curves published by the Connecticut investigators show that during several months there were greater increases in body weight of the rats receiving more iodide than among the controls on traces of the drug. These increases in body weight occur in about the same way and appear to be of about the same order of magnitude, namely, 8 or 10 per cent, as those reported by previous investigators. Assuming a benefit of this kind and degree to be correct and to hold good for man, it requires no stretch of the imagination to see that medication with iodide, practiced in various ways by physicians and the public the world over, with potentialities for good, may have an objective basis. Additional and more conclusive data are nevertheless desirable.

In another type of experiment, which ostensibly was designed to give the alleged beneficial effects of iodide an infallible test, Mitchell and his collaborators[3] of the Illinois Agricultural Experiment Station report negative results and deny the validity of most previous data. These investigators fed iodide to growing pigs, pouring the iodide on the morning feed in quantities equivalent to 1 grain (0.065 Gm.) of iodine daily; and to growing chickens, which received from 0.5 to 1 mg. daily per hundred grams of body weight. The Illinois investigators object to the group type of experiment, such as a group of three or five animals, frequently employed by previous workers. In their own experiments they used smaller groups, two pigs or three chickens, and practiced a peculiar selection of animals, so that each animal of a pair or triplet, one of which was the unmedicated control, was required to ingest the same amount of food daily. If an animal of a group did not eat the same amount, the food of the bigger eater was withheld. What this deliberate form of food restriction and equalization may mean for physiologic functions is not indicated, although it is assumed to be unobjectionable. In any case the conditions are not comparable with those of previous investigators who have employed the method of free choice in feeding, suitably controlled. Although the conclusions of the Illinois experimenters are unfavorable to the beneficial effects of iodide on growth and body weight in pigs and chickens, and on the assimilation of nitrogen, phosphorus and calcium in growing pigs, it seems that their conclusions can hold only for the special experimental conditions they imposed. The results might be, and in fact have been, different under other conditions. While it is possible that under other conditions the benefits of iodide might be due to effects on appetite, absorption, food consumption, or what not, this still leaves them within the scope of physiology.

Mathematical treatment of data alone does not necessarily make them physiologically accurate. Lest it be too readily assumed that all effects of iodide are mediated through the thyroid gland, a perusal of pharmacologic literature will indicate that iodide exerts many actions for which there is no reason to assume thyroid mediation, and yet the general metabolism may be affected. Thus it would appear that the reaction of body weight and growth of animals to continued administration of iodide in small doses is different under different experimental conditions. Additional animal experimentation to settle the question of beneficial effects of iodide appears desirable, for here clinical experimentation offers only impressions.

Current Comment

ACUTE PERITONITIS

The peritoneum, it has been said, is one of the most common sites of inflammation, not because it is especially susceptible to infection but because it is so often subject to attack. Although uninfected agents, such as blood, bile and urine, may cause peritoneal inflammation, bacteria or their toxins are the predominant etiologic factors concerned. The opinions as to the final cause of death in acute diffuse peritonitis have not been uniform. As intestinal paralysis, with obstruction of the bowel, is a common symptom, it has been regarded as a determining factor in fatal cases. Part of the difficulty in establishing the truth has also been due to the lack of suitable experimental analogues. Attempts to produce experimental peritonitis by the intraperitoneal introduction of bacteria into laboratory animals have not been entirely satisfactory. A presumptive explanation of some of the failures has been offered by Steinberg and Goldblatt.[1] Following the intraperitoneal injection of *B. coli* suspended in physiologic solution of sodium chloride, a large number of these organisms were found in the lymph (thoracic duct) and a relatively smaller number in the blood. Rapid passage of bacteria from the peritoneal cavity into the blood was associated with the recovery of the animal; hence bacteremia is not responsible for the death of dogs in acute *B. coli* peritonitis. However, when large numbers of virulent colon bacilli suspended in tragacanth are injected intraperitoneally the animals always die, and the outcome is not altered by direct drainage of the thoracic duct. Steinberg and Goldblatt formulated the hypothesis that the intraperitoneal retention of bacteria suspended in tragacanth favors the production of toxic substances, the absorption of which causes the death of the animal. When bacteria suspended in saline solution are injected intraperitoneally, the production of toxin in an appreciable quantity is prevented by the rapid passage of the bacteria into the blood stream, where they are destroyed. Further implication of bacterial toxins as the primary factor in producing death has been supplied by Steinberg.[2] A fatal peritonitis can readily be produced by the introduction of diphtheria bacilli in suspensions of tragacanth in saline solution. It can be prevented by the administration of antitoxin. The local inflammatory reaction per se apparently has no effect on the survival or death of the animal. This constitutes added evidence that death in acute diffuse peritonitis may, under some conditions at least, be due to passage of a bacterial toxin from the peritoneal cavity. Effective antitoxic treatment thus becomes a real desideratum.

SUGAR CONSUMPTION AND DIABETES

In discussions of the etiology of diabetes, it is usually admitted that the ultimate cause of the disease is not known. Obesity is at present regarded as the most important predisposing influence; and chronic dietary excesses usually precede obesity. Writers have from time to time identified dietary errors with ingestion of undue amounts of carbohydrate; and sugar in particular has been brought under suspicion. It happens, in fact, that the consumption of sugar has increased notably in many parts of the world while there has been an increase in the incidence and mortality of diabetes. This broad parallelism has led persons to assume a relationship of cause and effect between the dietary use of sugar and the occurrence of diabetes. Critical investigators have often pointed out the unconvincing nature of this sort of logic; and they have further noted statistical discrepancies that seem to invalidate the hypothesis of etiologic relationship. Joslin,[1] for example, has noted that diabetes is not conspicuous among cereal-eating orientals; that diabetes was quite as prevalent in Germany as in the United States at a period when our sugar consumption was much larger; and that England, with a much smaller sugar quota, has only slightly less diabetes. Joslin therefore ventures the conclusion that it is the excess of food rather than of carbohydrate that does the harm. Mills,[2] of the department of internal medicine at the University of Cincinnati College of Medicine, has recently made detailed comparisons of sugar per capita for five years (1923-1928), together with the death rate from diabetes for the most recent year obtainable, and the deaths expressed from diabetes as a percentage of the total deaths. These statistics fail to show any direct relationship between consumption of sugar and deaths from diabetes. Some countries with a high consumption of sugar, as Hawaii, Argentina and Cuba, have a relatively low death rate from diabetes, while some of the countries with a high death rate from diabetes, such as the Netherlands and the Union of South Africa, come fairly well down in the column of sugar consumption. It is to be noted, Mills adds, that, of the thirteen countries highest in consumption of sugar, eleven are found among the thirteen highest in death rate from diabetes. There are many discrepancies, however, indicating a lack of constant relationship between the consumption of sugar and the death rate from diabetes. In some that have shown a gradual but steady increase in the consumption of sugar for many years, there has occurred a recent decline in deaths from diabetes. Instead of unwarranted condemnation of a common food of the present day, it is probably more just to render the temporary verdict "not proven."

Association News

ANNUAL CONGRESS ON MEDICAL EDUCATION, LICENSURE AND HOSPITALS

Preliminary Program of Meetings to Be Held in Chicago, Feb. 16, 17 and 18, 1931

The next Congress on Medical Education, Licensure and Hospitals will be held in the Palmer House, Chicago, February 16, 17 and 18. The preliminary program is as follows:

CARE OF THE MENTALLY ILL IN THE UNITED STATES

(Monday Morning, February 16)
W. M. English, M.D., Presiding
President of the American Psychiatric Association, Brockville, Ont.

Mental Health as a National Problem
Hon. Ray Lyman Wilbur, M.D., Secretary of the Interior, and Chairman, Council on Medical Education and Hospitals, American Medical Association, Washington, D. C.

Federal Activities in the Care of the Mentally Ill
Walter L. Treadway, M.D., Assistant Surgeon General, Division of Mental Hygiene, U. S. P. H. S., Washington, D. C.

State Institutions and Their Relation to Medicine in General
Samuel W. Hamilton, M.D., Bloomingdale Hospital, White Plains, N. Y.

MENTAL HYGIENE

(Monday Afternoon, February 16)
William A. White, M.D., Presiding
Superintendent, Saint Elizabeth's Hospital, Washington, D. C.

Rôle of the State Hospital in Mental Hygiene
J. Allen Jackson, M.D., Superintendent, Danville State Hospital, Danville, Pa.

Rôle of Community Clinics in Mental Hygiene
George S. Stevenson, M.D., Director, Division on Community Clinics, The National Committee for Mental Hygiene, New York.

Child Guidance Clinics
Lawson G. Lowrey, M.D., Director, Institute for Child Guidance, New York.

PROBLEMS IN MEDICAL EDUCATION

(Monday Afternoon, February 16)
Henry S. Houghton, M.D., Presiding
Dean, State University of Iowa College of Medicine, Iowa City

The Present Trend of Medical Education
Charles P. Emerson, M.D., Dean, Indiana University School of Medicine, Indianapolis.

The Significance of Present Entrance Requirements
Wilburt C. Davison, M.D., Dean, Duke University School of Medicine, Durham, N. C.

The Premedical Years
(Speaker to be announced)

Methods of Examining Medical Students for Degrees: A Comparison with European Methods
Willard C. Rappleye, M.D., Director of Study, Commission on Medical Education, New Haven, Conn.

THE TEACHING OF PSYCHIATRY

(Tuesday Morning, February 17)
Adolf Meyer, M.D., Presiding
Psychiatrist-in-Chief, Johns Hopkins Hospital, Baltimore

Some Present-Day Trends in the Teaching of Psychiatry
Franklin G. Ebaugh, M.D., Director, Colorado Psychopathic Hospital, Denver

The Training of the Specialist in Psychiatry
C. Macfie Campbell, M.D., Director, Boston Psychopathic Hospital, Boston.

Psychiatry and the General Practitioner
H. Douglas Singer, Professor of Psychiatry, University of Illinois College of Medicine, Chicago.

PROBLEMS IN MEDICAL EDUCATION (Cont.)

(Tuesday Morning, February 17)
E. P. Lyon, M.D., Presiding
Dean, University of Minnesota Medical School, Minneapolis

The Continuous Session Plan
B. C. H. Harvey, M.D., Dean of Medical Students, Graduate School of Medicine of the Ogden Graduate School of Science, University of Chicago, Chicago.

The Preceptor System Plan
Llewellyn R. Cole, M.D., Graduate Hospital of the University of Pennsylvania Graduate School of Medicine, Philadelphia.

A Plan for Training the Medical Student in General Practice
Harry E. Kaplan, M.D., Stockton, Calif.

Deficiencies in the Teaching of Surgery
W. T. Coughlin, M.D., Professor of Surgery and Director of the Department of Surgery, St. Louis University School of Medicine, St. Louis.

FEDERATION OF STATE MEDICAL BOARDS OF THE UNITED STATES

FIRST SESSION

MEDICAL EDUCATION AND LICENSURE

(Tuesday Morning, February 17)
Charles B. Pinkham, M.D., Presiding
President, Federation of State Medical Boards of the United States, Sacramento, Calif.

Responsibility of Medical Schools to Registration and Licensure
Burton D. Myers, M.D., Chairman, Executive Council, Association of American Medical Colleges, Bloomington, Ind.

Registration of Foreign Medical Graduates in the United States
Willard C. Rappleye, M.D., Director, Commission on Medical Education, New Haven, Conn.

State Board Examinations
William Jepson, M.D., Chairman, Iowa State Board of Medical Examiners, Sioux City.

Discussion: J. Stewart Rodman, M.D., Medical Secretary, National Board of Medical Examiners, Philadelphia; G. M. Williamson, Secretary, North Dakota State Board of Medical Examiners, Grand Forks; J. H. J. Upham, M.D., Member, Ohio State Medical Board and Dean, Ohio State University, College of Medicine, Columbus.

FEDERATION OF STATE MEDICAL BOARDS OF THE UNITED STATES

SECOND SESSION

STATE BOARD PROBLEMS

(Tuesday Afternoon, February 17)
Charles B. Pinkham, M.D., Presiding

Operation of the Basic Science Law in Wisconsin
J. Gurney Taylor, M.D., Member, Wisconsin State Board of Medical Examiners, Milwaukee.

Nonmedical Directors of State Departments of Public Welfare and Licenses
H. J. Lehnhoff, M.D., Secretary, Nebraska Board of Medical Examiners, Lincoln.

Who Shall Be Permitted to Continue the Practice of Medicine?
F. C. Warnshuis, M.D., Secretary, Michigan Board of Registration in Medicine, Detroit.

Discussion: I. D. Metzger, M.D., President, Pennsylvania Board of Medical Education and Licensure, Pittsburgh; Henry M. Fitzhugh, M.D., Secretary, Maryland Board of Medical Examiners, Baltimore; William Whitridge Williams, M.D., Secretary, Colorado Board of Medical Examiners, Denver.

GRADUATE MEDICAL EDUCATION

(Tuesday Afternoon, February 17)
C. C. Bass, M.D., Presiding
Dean, Tulane University of Louisiana School of Medicine, New Orleans

The Training of the Specialist
William J. Mayo, M.D., Mayo Clinic, Rochester, Minn.

Some "Whats" and "Whys" in Graduate Medical Education
G. H. Meeker, M.D., Dean, University of Pennsylvania Graduate School of Medicine, Philadelphia.

Extension Courses for Rural Physicians
Joe P. Bowdoin, M.D., Deputy Commissioner, State Board of Health, Atlanta, Ga.

The Future of Graduate Medical Education in the United States
James S. McLester, M.D., Member, Council on Medical Education and Hospitals, American Medical Association, and Professor of Medicine, University of Alabama School of Medicine, Birmingham.

HOSPITAL PROBLEMS

(Tuesday Afternoon, February 17)
(Presiding officer to be announced)

The Hospital, Medical College, and Intern
A. C. Bachmeyer, M.D., Superintendent, Cincinnati General Hospital, Cincinnati.

The Hospital Training of Interns
H. L. Foss, M.D., Surgeon-in-Chief, George F. Geisinger Memorial Hospital, Danville, Pa.

Hospitals and the Law
Thomas V. McDavitt, J.D., Bureau of Legal Medicine and Legislation, American Medical Association, Chicago.

Discussion: Fred G. Carter, M.D., Superintendent, Ancker Hospital, St. Paul.

THE TEACHING OF PEDIATRICS

(Wednesday Morning, February 18)
Isaac A. Abt, M.D., Presiding
Professor of Pediatrics, Northwestern University Medical School, Chicago

Present Status of Pediatric Teaching in Medical Schools
Bordon S. Veeder, M.D., Professor of Clinical Pediatrics, Washington University School of Medicine, St. Louis.

The Position of Pediatrics in Medicine and Medical Teaching
Clifford S. Grulee, M.D., Professor of Pediatrics, Rush Medical College, University of Chicago, Chicago.

What [illegible] Department of Pediatrics in a Medical School
A. [illegible], B. K. Rachford Professor of Pediatrics, College of Medicine, Cincinnati.

FEDERATION OF STATE MEDICAL BOARDS OF THE UNITED STATES

THIRD SESSION

MEDICAL REGISTRATION AND LAW ENFORCEMENT

(Wednesday Morning, February 18)
Harold Rypins, M.D., Presiding
President-Elect, Federation of State Medical Boards of the United States, Albany, N. Y.

Distribution of Physicians in Kentucky
Dr. W. L. Chambers, University of Kentucky, Louisville.

Relation of the Organized Profession to Medical Registration and Enforcement
Walter F. Donaldson, M.D., Member, Council on Medical Education and Hospitals, American Medical Association, and Secretary, State Medical Society of Pennsylvania, Pittsburgh.

The Control of the Unlicensed Practitioners
Hon. Sol. Ullman, Deputy Attorney General of New York, Albany.

The American System of Medical Registration and Licensure
H. M. Platter, M.D., Secretary, Ohio State Medical Board, Columbus.

Discussion: Arthur T. McCormack, M.D., Secretary, Kentucky State Board of Health, Louisville; Thomas J. Crowe, M.D., Secretary, Texas Board of Medical Examiners, Dallas; John R. Neal, M.D., Member, Professional Committee, Department of Registration and Education of the State of Illinois, Springfield.

American Conference on Hospital Service

FIRST SESSION

CONVALESCENT CARE

(Wednesday Morning, February 18)
Harry E. Mock, M.D., Presiding
President, American Conference on Hospital Service, Chicago

Survey of Convalescent Care in the United States
E. H. L. Corwin, Ph.D., Chairman, Committee on Convalescent Care, American Conference on Hospital Service, New York.

Report of Committee to Study Possibilities for Convalescent Care
James A. Britton M.D., Chicago.

(Other subjects and speakers to be announced later)

Joint Session of the American Conference on Hospital Service and the Council on Physical Therapy of the American Medical Association

(Wednesday Afternoon, February 18)
Merritte W. Ireland, M.D., Presiding
The Surgeon General, U. S. Army, and Member, Council on Medical Education and Hospitals, American Medical Association, Washington, D. C.

Physical Therapy and Teaching Hospitals
(Speaker to be announced.)

Occupational Therapy
W. R. Dunton, Jr., M.D., Harlem Lodge, Catonsville, Md.

Rehabilitation and Convalescent Care
E. H. L. Corwin, Ph.D., Executive Secretary, Committee on Public Health Relations, New York Academy of Medicine, New York.

Discussion: Harry E. Mock, M.D., Chicago.

ORGANIZATIONS REPRESENTED

Participating in the congress of the Council on Medical Education and Hospitals of the American Medical Association will be the Federation of State Medical Boards of the United States, and the American Conference on Hospital Service. The Central Council for Nursing Education will hold an institute for lay boards of hospitals and public health nursing organizations, on Tuesday, February 17. The Council on Medical Education and Hospitals takes this opportunity to invite every one who may be interested to attend the three-day conference, whether he receives a personal invitation or not.

REDUCED RAILWAY FARES

In order to obtain the reduced rate of one and one-half fares for the round trip to Chicago, it will be necessary to secure at least 150 receipts showing that full fares have been paid on the trip to Chicago. The reduced fares, if enough receipts are secured, will apply to friends and relatives as well as to those regularly invited to the conference.

Be sure to obtain *a certificate receipt for your fare to Chicago,* however small it may be, so that those coming from distant states or across the continent will have the benefit of the one-half return fare. This receipt, after being countersigned by an official of the passenger associations, who will be present at the Palmer House, will entitle its holder to the reduced fare on the return trip.

DINNERS

All in attendance at the congress, ladies included, will be invited to dinners as follows:

Monday Evening. 7 p. m. The Council on Medical Education and Hospitals will hold a joint dinner with the Central Council on Nursing Education. Toastmaster, Hon. Ray Lyman Wilbur, Secretary of the Interior. Principal speaker, Dr. Henry A. Christian, Hersey Professor of the Theory and Practice of Physic, Harvard University Medical School. Informal.

Tuesday Evening. 6:30 p. m. Federation Dinner. John W. MacConnell, M.D., Davidson, North Carolina, vice president, presiding. Address of the president, Charles B. Pinkham, M.D., Sacramento, Calif. Informal.

CONTRIBUTIONS TO PERSHING MEMORIAL

The response to the request for contributions for the Medical Salon in Pershing Hall, Paris, has not been as prompt or as extensive as it should be. It is to be hoped that the medical profession will see the desirability of aiding this cause. It is far better to have small contributions from many physicians than to depend on a few to make up the total. Up to noon of December 15, additional contributions were received from the following:

Thomas K. Davis, M.D., New York
Howard Fox, M.D., New York
Francis M. O'Gorman, Buffalo
Macy L. Lerner, M.D., Rochester, N. Y.
J. L. Lattimore, M.D., Topeka, Kan.
J. H. Walsh, M.D., Chicago
Charles H. Hulick, M.D., Shelbyville, Ill.
James C. Ferguson, M.D., St. Paul
Harvey B. Stone, M.D., Baltimore
G. Willis Bass, M.D., Minneapolis
Henry Holm, M.D., Detroit
S. N. Trockey, M.D., Chicago
Donald D. Forward, M.D., Ashtabula, Ohio
Mary Harley, M.D., Sweet Briar, Va.
Allen H. Bunce, M.D., Atlanta, Ga.
Wallace C. Dyer, M.D., Evansville, Ind.
Harmon L. Stanton, M.D., Evansville, Ind.
Robert Acker, M.D., South Bend, Ind.
W. H. Wilmer, M.D., Baltimore
James McCrea, M.D., Fulda, Minn.
J. Scott Oehrle, M.D., Monongahela, Pa.
Orlando H. Petty, M.D., Philadelphia
R. E. Seitz, M.D., Bozeman, Mont.
Fred E. Clow, M.D., Wolfeboro, N. H.
Eugene J. Asnis, M.D., Philadelphia
J. Forrest Burnham, M.D., Lawrence, Mass.
Clifford J. Pearsall, M.D., Salt Lake City
Ira I. Kaplan, M.D., New York
O. B. Pomeroy, M.D., Cleveland
Walter A. Strayer, M.D., Glenshaw, Pa.
H. H. Amsden, M.D., Concord, N. H.
Walter L. Bierring, M.D., Des Moines, Iowa
George F. Glass, M.D., Cleveland
Reginald Fitz, M.D., Boston
Alfred Meyer, M D., New York
W. Eugene Currier, M.D., Leominster, Mass.
Albert Evans, M.D., Boston
Frank Brooks Foster, M.D., Peterborough, N. H.
Joseph P. McMahon, M.D., Milwaukee
David P. Waldman, M.D., New York
Esther M. Closson, M.D., Tucson, Ariz.
Max Dreyfoos, M.D., Cincinnati
M. L. Holliday, M.D., Fillmore, Mo.
Joseph Baum, M.D., Far Rockaway, N. Y.
J. J. Hood, M D., Cicero, Ill.
George W. Norris, M.D., Philadelphia
Mitchell Seltzer, M.D., Dallas, Texas
F. A. Long, M.D., Madison, Neb.
Vincent S. Mancuso, M.D., Detroit
W. R. Roberts, M.D., Cissna Park, Ill.
R. R. McHenry, M.D., Norfolk, Va.
Henry Abrahm, M.D., San Francisco
Henry M. Mills, M.D., Brooklyn
W. H. Garrison, M.D., White Hall, Ill.
Franklin W. Mathewson, M.D., Oakdale, Pa.
A. Szwajkart, M.D., Chicago
Damon B. Pfeiffer, M.D., Philadelphia
Joel E. Goldthwait, M.D., Boston
W. E. Carson, M.D., Pittsburgh
G. S. Murray, M.D., Columbus, Ga.
James F. Rooney, M.D., Albany, N. Y.
James B. Ungles, M.D., Satanta, Kan.
Marshal Fabyan, M.D., Boston
William T. Myers, M.D., Aldrich, Mo.
P. C. Coleman, M.D., Colorado, Texas
L. P. Warren, M.D., Wichita, Kan.
A. M. Purves, M.D., Des Plaines, Ill.
J. E. Keeling, M.D., Waldron, Ind.
W. Q. Skilling, M.D., Lonaconing, Md.
Zoda D. Lumley, M.D., Wood River, Ill.
L. B. McBrayer, M.D., Southern Pines, N. C.
James W. Smith, M.D., New York
Winfield Scott Cleland, M.D., Delta, Colo.
Ernest S. du Bray, M.D., San Francisco
R. de R. Barondes, M.D., San Francisco
Salinas, Monterey Chapter, Disabled American Veterans World War, California
Robert Emery Brennan, M.D., New York
Charles T. Francis, M.D., Fairmont, W. Va.
John H. Peck, M.D., Des Moines, Iowa
Paul M. Allis, M.D., Lewistown, Pa.
Abby N. Little, M.D., Laconia, N. H.
Friend, Peoria, Ill.
Albert A. Hornor, M.D., Boston
William E. Stevens, M.D., San Francisco
E. G. Brandenberger, M.D., Detroit
Leonard F. Bender, M.D., Frankford, Pa.
Richard Reeser, M.D., Columbia, Pa.
George E. Alleman, M.D., Altoona, Pa.
C. W. Mack, M.D., Livermore, Calif.
Ira Cohen, M.D., New York
Delaware County Medical Society, Chester, Pa.
George H. Garrison, M.D., Oklahoma City
J. R. Knowles, M.D., North Station, Boston
Samuel Steiner, M.D., Philadelphia
S. Fosdick Jones, M.D., Denver
Clifford Grulee, M.D., Chicago

THE PHILADELPHIA SESSION

Announcement of Exhibit under the Auspices of the Section on Diseases of Children

The officers of the Section on Diseases of Children have appointed the following as members of the Committee on Section Exhibit: T. C. Hempelmann, M.D., St. Louis; Joseph Stokes, Jr., M.D., Philadelphia, and F. Thomas Mitchell, M.D., chairman, Memphis, Tenn.

The committee announces that it is desirous of having a creditable and enlightening section exhibit. The topics suggested by the committee are:

(*a*) Relation Between Underweight and Malnutrition.
(*b*) Diet in Pediatric Practice.
(*c*) Selected Exhibits of Educational and Research Character.

The members of the specialty are asked by the committee to determine whether or not they have work suitable for exhibition and, if so, to communicate with the committee chairman, Dr. F. Thomas Mitchell, 376 South Bellevue Street, Memphis, Tenn. All applications must be made on the regular application form, which is the one required by the A. M. A. Committee on Scientific Exhibit. A circular letter giving information concerning this exhibit, together with the usual application blank, has been mailed to those who have registered in the section during the last three years and to subscribers to the Jacobi Fund. Those who have not registered in this section but who are interested in such an exhibit may obtain a circular letter and application blank by sending the request to Dr. Mitchell or to the Director, Scientific Exhibit, 535 North Dearborn Street, Chicago. Applications should be filed not later than Feb. 10, 1931, with Dr. Mitchell.

Committee Appointments

Dr. George C. Yeager, chairman of the Local Committee on Arrangements, has appointed Dr. Frederick S. Baldi chairman of the Subcommittee on Hotels; Dr. Joseph C. Doane chairman of the Subcommittee on Publicity, and Dr. Fred D. Weidman chairman of the Subcommittee on Scientific Exhibit.

MEDICAL BROADCAST FOR THE WEEK

American Medical Association Health Talks

The American Medical Association broadcasts at 10 a. m. on Monday, 10:15 on Tuesday, 10:30 on Thursday and 10 on Saturday, over Station WBBM (770 kilocycles, or 389.4 meters).

The program for the week is as follows:

December 22. What Is Tuberculosis?
December 23. The Century's Greatest Story.
December 27. The Wooden Indian.

Five minute health talks may be heard over the Columbia Broadcasting System daily except Sundays and holidays, from 12 to 12:05 p. m.

The program for the week is as follows:

December 22. Is It Blue Monday or Rose Monday?
December 23. Don't Blame the Weather.
December 24. The Disease That Deforms.
December 26. The Pace That Kills.
December 27. Save the Children from Scarlet Fever.

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest: such as relate to society activities, new hospitals, education, public health, etc.)

CALIFORNIA

Illegal Practitioner Jailed.—Augustin Ocampo, Los Angeles, was arrested, November 5, on a charge of practicing medicine without a license. He pleaded guilty in municipal court, was sentenced to 180 days in jail and is now serving the sentence. January 10, he pleaded guilty on two counts to violation of the state medical practice act and was given a thirty day suspended sentence on each count. Ocampo claimed that he practiced in the city of Mexico for twelve years, coming to California in 1929.

Society News.—The San Francisco County Medical Society was addressed, November 18, by Dr. Samuel H. Hurwitz on "Asthma and Occupation"; Dr. Adolph Berg presented a case of acrodynia, and Drs. Edward B. Shaw, Huldah E. Thelander and Margaret A. Limper, motion pictures demonstrating the early diagnosis of poliomyelitis.——The Los Angeles County Medical Association was addressed, December 5, by Dr. William Gerry Morgan, Washington, D. C.; Dr. Joseph Colt Bloodgood, Baltimore, spoke on "The Importance for the Patient of the Diagnosis of Cancer and Lesions That Are Not Cancer by Both the General Practitioner and the Specialist."——Drs. Albert L. Mathieu, Portland, and Oscar Donovan Johnson, Los Angeles, addressed the Los Angeles Obstetrical Society, December 9, on "The Aschheim-Zondek Pregnancy Test" and "Uterotubal Insufflation with Kymographic Tracings," respectively; Dr. Rudolph Marx presented a case report on acardiacus amorphus.——Dr. Edward B. Towne, San Francisco, addressed the San Diego County Medical Society, December 9, on "Roentgen Ray in Diagnosis and Localization of Tumors of the Brain."——Dr. Joseph C. Aub, Harvard University Medical School, Boston, addressed the San Diego Academy of Medicine, December 8, on "The Rôle of Inorganic Salts in Internal Medicine."——Dr. Oliver Hazard Perry Pepper, University of Pennsylvania School of Medicine, Philadelphia, will give the annual Scripps Metabolic Clinic Lectures in San Diego, January 8-10. He will deliver an evening lecture in La Jolla, January 10, on types of anemia, exclusive of pernicious anemia.——Dr. Paul J. Hanzlik, professor of pharmacology, Stanford University School of Medicine, San Francisco, gave a series of lectures, December 16-19, before the San Diego Academy of Medicine and the Long Beach Academy of Medicine, on bismuth compounds in antisyphilitic therapy, metallotherapy of edema, intravenous therapy and colloidal dyes in intoxications.——Dr. Albert H. Rowe, Oakland, addressed the Alameda County Medical Association, December 15, on "Bronchial Asthma."

New Life Sciences Building at University of California.—The work of moving thirteen departments from eleven wooden frame buildings into the new fireproof Life Sciences Building at the University of California was completed in July. The building, which is said to be the largest building devoted to academic purposes on any campus in America, is about 500 feet long, 250 feet wide, five stories high, and in the form of a rectangle built around a court. There are 560 offices, laboratories, classrooms, auditoriums, and museum and library rooms, one auditorium seating 560 people and two smaller rooms each seating 208. The departments housed in the building are bacteriology, anatomy, biochemistry, botany, household science, hygiene, vertebrate zoology and museum of vertebrate zoology, physiology, plant nutrition, psychology and zoology, and three bureaus of the state board of health maintain offices and laboratories there. The building is constructed of reinforced concrete with natural finish on the outside. Interior partitions are made of sound-proof hollow tile painted white. The classrooms and auditoriums are finished in acoustic plaster.

ILLINOIS

Personal.—The Ottawa Tuberculosis Sanatorium was recently purchased by Dr. Royal W. Dunham.

Chicago

Reduction in Rates for Nurses.—Under a plan announced by the Chicago Medical Society, the services of trained nurses may be obtained for twenty hours at a cost of one dollar more than the prices previously charged for twelve hours. The rate will be $8 for a twenty hour day. The present rate of $7 for a twelve hour day remains as at present. The plan also makes available the practical nursing and undergraduate nursing service at one-third less cost than graduate service. Hourly nursing service will be obtainable at a rate of $2 flat for the first hour and $1 each hour thereafter when the family physician believes this will be sufficient. The new rates result from the fact that the public at present is disposed to cut nursing time to the minimum. More cases are now being cared for by relatives and neighbors, it is reported, than at any time in the last ten years. Already 60 per cent of the demand is for twenty hour service and only nurses who exemplify the highest standard are suitable for this. The new service is available through the nurses' registry of the Chicago Medical Society.

Society News.—Dr. Richard B. Stout, Madison, Wis., addressed the Chicago Surgical Society, November 7, on "Spinal Anesthesia Volume Control Technic."——The Chicago Pathological Society was addressed, November 10, among others, by Drs. Evan M. Barton and Lloyd Catron on "Dissecting Aneurysm of the Aorta" and "Leiomyosarcoma of the

Pleura," respectively.——Dr. Grafton Elliot Smith of the Institute of Anatomy, University College, London, England, addressed a joint meeting of the Institute of Medicine of Chicago and the University of Chicago, November 26, on "The Peking Man and the Evolution of the Human Brain."——The eighth annual joint meeting of the Illinois and Chicago societies of industrial medicine and surgery was addressed, December 3, by Drs. Hiram W. Orr, Lincoln, Neb., and Henry W. Newman, Cincinnati, on "Osteomyelitis" and "Nonsurgical Industrial Medicine," respectively.——The first meeting of the Chicago Society of Allergy will be addressed, December 22, by Drs. Samuel M. Feinberg and Harry L. Huber on "Historical Aspects of Allergy" and "Variations in Tolerance to Pollen Extracts," respectively.——Dr. James B. Herrick gave a brief memorial tribute to Dr. Charles E. Paddock before the Chicago Gynecological Society, December 19. Other speakers were: Drs. Alexander G. Gabrielianz on "Spinal Anesthesia in Gynecology," and Jacob P. Greenhill, "Rupture of a Corpus Luteum with Intra-Abdominal Hemorrhage."——The Chicago Roentgen Society was addressed, December 10, by Drs. George T. Palmer, Springfield, Ill., on "X-Ray Diagnosis of Tuberculosis," and William A. Evans, Detroit, "Indications for and Results of Surgical Treatment of Pulmonary Lesions as Observed Roentgenologically"; Dr. Benjamin Goldberg spoke on "Roentgenologic Aspects of Pulmonary Tuberculosis in Childhood."——Among others, Dr. Sol R. Rosenthal addressed the Chicago Pathological Society, December 8, on "Aneurysm of the Cystic Artery and Melanocarcinoma of the Gallbladder."——Among the speakers who addressed the Chicago Tuberculosis Society, December 11, were: Drs. Robert G. Bloch on "Experimental Infection with Tuberculosis"; Russell D. Herrold, "Laboratory Diagnosis of Tuberculosis," and Ralph B. Bettman, "Feasibility of Intrapleural Operations."——The Chicago Society of Internal Medicine was addressed, December 15, among others, by Dr. Joseph L. Miller on "Classification, Etiology and Pathology of Chronic Arthritis."

MASSACHUSETTS

Society News.—Dr. Walter B. Cannon, Boston, addressed the Harvard Medical Society, December 9, on emotional increase of heart rate, and Dr. John M. Flynn, on sulphur metabolism.——Dr. Harry M. Zimmerman, Yale University School of Medicine, New Haven, Conn., spoke before the New England Pediatric Society in Boston, December 12, on "Nonpurulent Encephalitis in Children."——Dr. Harry Blotner, Boston, addressed the Haverhill Medical Club, December 4, on "Periodic Health Examinations."

Personal.—Dr. James Arthur Gage, Lowell, recently retired from the practice of medicine and surgery; he was honored at a testimonial banquet given by the Middlesex North District Medical Society, December 10.——Dr. Otto Folin, Hamilton Kuhn professor of biologic chemistry at Harvard University Medical School, recently received the Scheele Medal of the Chemical Society of Stockholm. He is the first recipient of that medal. Announcement of its award was made at the dedication of the building of the Rockefeller Institute for Biochemistry in Stockholm.

MISSOURI

Milk Commission Discontinues Milk Distribution.—After twenty-six years of service in distributing pure milk for infant feeding among poor families, the St. Louis Pure Milk Commission recently turned over this function to four local social agencies. The laboratory of the commission was opened in June, 1904, for sterilizing and modifying milk, which was distributed to congested districts to be dispensed on prescription of physicians. During the twenty-six years, 8,952,612 bottles were distributed. An infant welfare station opened in 1906 under the auspices of the commission is said to have been the first of these stations in the United States.

Society News.—Dr. Samuel R. Cunningham, Oklahoma City, addressed the Jackson County Medical Society, December 9, on "Skeletal Traction in the Treatment of Fractures of Long Bones."——The South East Missouri Medical Association held its fifty-fourth annual meeting in Poplar Bluff, October 7-8; the following speakers and their subjects were included in the program: Drs. Daniel H. Hope, Cape Girardeau, "Ectopic Pregnancy, Causes and Treatment"; John D. Hayward, St. Louis, "Fundamentals in Diagnosis of the Acute Abdomen," and Neil S. Moore, St. Louis, "Late Syphilis Involving the Genito-Urinary Organs." The next annual meeting will be held at Campbell.

NEBRASKA

Personal.—A portrait of Dr. John E. Summers, Omaha, a gift of medical and lay friends, was unveiled at the Clarkson Hospital, Omaha, November 2. Dr. Donald Macrae, Jr., Council Bluffs, Iowa, spoke of the life work of Dr. Summers. He has been president of the Nebraska State Medical Association, the Missouri Valley Medical Association and the Western Surgical and Gynecological Society.

Society News.—Physicians of Dawes County and the surrounding territory met at Chadron, November 12, and organized the North-West County Medical Society; Drs. Albert L. Cooper, Scottsbluff, and Frank B. Young, Gering, gave an illustrated lecture on "Some Aspects of Paleopathology"; the second Wednesday of the month was chosen as the date of meeting.——The Cheyenne-Kimball County Medical Society was addressed in Sidney, November 14, by Drs. Dee L. Abbott, Sidney, and Joseph B. Pankau, Dalton, on "Anaphylaxis" and "Treatment of Pneumonia," respectively.

Testimonial Dinner to Dr. Orr.—Members of the Lancaster County Medical Society tendered a testimonial dinner, November 4, to Dr. Hiram W. Orr, Lincoln, on his completion of twenty-five years of service at the Nebraska Orthopedic Hospital. A testimonial inscription bearing the names of all those present at the dinner was presented to Dr. Orr. Among others, Dr. John P. Lord, Omaha, reviewed the history and early struggles of the orthopedic hospital, of which he was the first surgeon, with Dr. Orr as his assistant. Dr. Orr was president of the Nebraska State Medical Society in 1920.

NEW YORK

Society News.—The Medical Society of the County of Albany was addressed, December 15, by Dr. Charles K. Winne, Jr., on "Serum Therapy in Scarlet Fever."——The Queensboro Pediatric Society was addressed, December 11, at Forest Hills, Long Island, by Drs. Benjamin Kramer, Brooklyn, on "Rickets—History, Pathology, Diagnosis and Treatment," and Lee W. Thomas, "The Maintenance of Child Health."

Eastman Gives Dental Clinic to Stockholm.—George Eastman, Rochester manufacturer, is reported to have given $1,000,000 to the city of Stockholm, Sweden, for a dental dispensary similar to the Rochester Dental Dispensary and to those recently established by Mr. Eastman in London and Rome. The Stockholm clinic will include one feature not provided for in the other foreign cities, a school for dental hygienists similar to that of the Rochester dispensary. The Chicago *Tribune* says that the gift has been accepted and a site chosen for the building.

New York City

Historic Microscope.—A microscope thought to be nearly 200 years old has been presented to the New York Academy of Medicine by Dr. Warren Coleman. The case bears a brass plate on which is engraved: "This Microscope brought from Holland by Jan Evertson Keteltas in the year 1649 is given by his Descendant Henry Keteltas Aug 12th 1895 to Doctor Warren Coleman as a pleasant remembrance." According to a plate inside the case, the instrument was made by Benjamin Cole, who is known to have entered business in London in 1751. Authorities believe, therefore, that the microscope given to Dr. Coleman was not the one originally brought to this country in 1649, but one that replaced it about 100 years later.

Loss of Light Due to Smoke.—A report recently issued by the U. S. Public Health Service described the loss of light due to smoke on Manhattan Island with special reference to its relation to the nature of the weather, the relative humidity of the air and the velocity and direction of the wind. The investigations were made simultaneously on the roof of the U. S. Marine Hospital, 67 Hudson Street, which is 79 feet above street level and 93 feet above high water, at the lower end of Manhattan Island where the air is unusually smoky and on the roof of a building at the U. S. Quarantine Station on Staten Island, in lower New York Bay, 35 feet above the ground and 40 feet above high water, located about 9 miles south of the marine hospital, where the air was comparatively clear. The instruments used for recording daylight consisted of photo-electric cells and the recording potentiometer. The comparison of results showed that there was a large relative loss of light at the Hudson Street hospital due to smoke, in some cases greater than 50 per cent. The average percentage loss for the whole year was 16.6 for clear days; 34.6 for cloudy days, and 21.5 for all days. The average percentage loss of light throughout the year was 30.2 at 8:30 a. m., 16.5 at 1:30 p. m., and 21.0 at 3:30 p. m. The percentage losses increased and decreased with the relative humidities. For clear days the greatest average monthly percentage loss was 23.1 in November and the least 12.1 in May, with corresponding average relative humidities of 64.6 and 39.0 per cent. For cloudy days these values were 52.7 in September and 24.6 in December with corresponding relative humidities of 99.4 and 85.9 per cent. The percentage loss of light was found to be 1.5 times as great for cloudy days as for clear days for relative humidities between 40 and 80 per cent and for wind velocities between 10.0 and 19.9 miles per hour.

Society News.—At the annual meeting of the Frontier Nursing Service, January 15, at Mecca Hall, Mrs. Mary Breckinridge, director of the field work, will present motion pictures in connection with her annual report of the work in the Kentucky mountains.——Dr. Joseph Colt Bloodgood will address the International and Spanish Speaking Association of Physicians, Dentists and Pharmacists, December 26, on the education of the public in malignant and nonmalignant diseases and the popularization of periodic health examinations. The society was addressed, November 28, by Dr. Anthony Bassler on "Intestinal Toxemia," illustrated, and Dr. Oswald S. Lowsley, "Intravenous Pyelography with Uroselectan."——Dr. Byron H. Goff addressed the Brooklyn Gynecological Society, December 5, on "A Histologic Study of the Vaginal Walls in Cystocele and Rectocele."——Dr. George R. Minot, Boston, will give the seventh of a series of afternoon lectures at the New York Academy of Medicine, January 9, on "Treatment of Anemia." The fifth lecture was delivered by Dr. Alfred F. Hess, December 12, on "Therapeutics of Ultraviolet Light," and the sixth by Miss Frances Perkins, state industrial commissioner, Albany, December 19, on "Occupational and Industrial Diseases."——Dr. Merrill C. Sosman, Boston, addressed the New York Roentgen Society, December 15, on "The Value of the X-Rays in the Diagnosis of Intracranial Tumors."——At a meeting of the New York Pathological Society, December 17, addresses were delivered by Drs. Arthur J. Lapovsky and Boris Kwartin on "Ruptured Ovarian Pregnancy"; Benjamin M. Vance on "Injuries of the Pons"; Helen Sinclair Pittman on "An Evaluation of the Erythrocyte Sedimentation Reaction as a Routine Diagnostic Procedure in the General Hospital"; Nicholas M. Alter, Marshall C. Pease, Jr., and Adolph G. DeSanctis on "Albers-Schoenberg Disease; 'Marble Bones.'"——The Medical Association of the Greater City of New York conducted a symposium on medical hydrology, December 15, with Drs. William Edward Fitch, Bedford Springs, Pa., and Allen W. Holmes, Watkins Glen, N. Y., as the speakers.

OHIO

Personal.—Dr. Vera C. Iber, formerly of Eaton, has been appointed head of the department of women's diseases at the Mayo Clinic, Rochester, Minn.——Dr. George Bourne Farnsworth, for twenty years on the faculty of Western Reserve University School of Medicine, has resigned as assistant professor of obstetrics. He will retire from active practice to devote his time to travel.

Hospital News.—A new $500,000 pediatric research building has been opened at Children's Hospital, Cincinnati. Dr. Albert Graeme Mitchell is director of the hospital.——A new division devoted to neuropsychiatry was recently opened at Mercy Hospital, Canton, under the supervision of Dr. John D. O'Brien. Patients may be referred for supervision and treatment or for consultation only; when patients are referred for treatment, the hospital invites the physician to act as consultant. The purpose of the hospital is to make available sound information on mental health and to help bring neuropsychiatric service within the reach of persons of moderate means.

Drought-Stricken Cities Ask Aid.—Four Ohio cities, reported to be suffering severely from the long continued drought and in danger of typhoid epidemics, have appealed to the state department of health for relief. Barnesville, largest of the towns, had only two weeks' supply of water December 4. By laying an emergency pipe line to an abandoned mine, engineers of the health department were able to increase the supply to last about thirty days. Caldwell, a town of 1,800 persons, was said to have no water. Until recently the town had pumped sewage flow from a creek for water to fight fires, but with the coming of cold weather this supply was frozen. Blanchester and Greenwich are the other towns in which conditions are said to be alarming. Unless some other means of relief is found, it will be necessary to transport water from other towns.

PENNSYLVANIA

Society News.—The Cambria County Medical Society was addressed in Johnstown, December 11, by Dr. Robert C. Davis, on "Treatment of Varicose Veins"; Dr. Olin G. A. Barker delivered a lecture and presented motion pictures on Russia; Dr. Henry K. Mohler, Philadelphia, addressed the society, November 13, on "Disturbances of Carbohydrate Metabolism in Relation to Cardiovascular Disease."——Raymond Adams Dutcher, head of the department of biochemistry at Pennsylvania State College, State College, addressed the Lycoming County Medical Society, December 12, on "Vitamins in Human and Animal Nutrition."

TENNESSEE

Hospital News.—A Negro unit as an addition to the Knoxville General Hospital was assured when the city council of Knoxville voted an appropriation of $25,000 toward the cost, November 28, it is reported in the Knoxville *Journal*. The Julius Rosenwald Foundation contributed $50,000 and the remainder of the fund has been contributed from local sources. Negro physicians, interns and nurses will comprise the staff of the unit, in accordance with an agreement with the Rosenwald Foundation.

VIRGINIA

Personal.—Henry G. Parker, city bacteriologist of Norfolk since 1917, and recently assistant director of public welfare, has been made director of public welfare to succeed Dr. Powhatan S. Schenck, who is on indefinite leave of absence on account of ill health. Dr. Frank H. Hancock, physician to the municipal hospital, has recently been installed as health commissioner. Dr. Schenck had served in the dual capacity since 1918.

University News.—An anonymous gift of $2,500 for purposes of chemicomedical research at the Medical College of Virginia, Richmond, has been announced. This gift will make possible a full time worker for one year in the department of chemistry. Other departments of the school of medicine will fully cooperate in the special line of study to be undertaken and will share in responsibility for the work. William John Gies, Ph.D., New York, was the chief speaker at the medical college on founder's day, December 1, on the ninety-third anniversary of the institution. His subject was "Progress in Health Services."

WEST VIRGINIA

Society News.—"Technic of Elective Version with Lantern Slide Demonstration Including Immediate Repair of Birth Canal Injuries Following Delivery" was the subject of Dr. Irving W. Potter, Buffalo, before the Ohio County Medical Society, Wheeling, December 5. Dr. Eugene P. Pendergrass, Philadelphia, addressed the society, November 21, on "X-Ray Diagnosis of Diseases of the Upper Respiratory Tract."

Licensure Requirements Raised.—The Public Health Council at a meeting at Morgantown, November 20-22, adopted the following regulations raising the requirements for the licensure of physicians: 1. All applicants for license by examination shall be required to have served one year of internship in a class A hospital before admission to the examination. 2. License by reciprocity will be issued only to those who have passed an examination subsequent to internship before the examining board of the state from which the application is filed. 3. Under no circumstances will applicants be admitted to the examination who have not received their professional degree. The regulation concerning reciprocity is not retroactive, it was stated.

WISCONSIN

Testimony of Physicians.—A proposal to change court rules to compel physicians to testify concerning information from patients in cases involving questions of sanity was defeated in the Wisconsin supreme court recently. The court held that the present procedure is a matter of substantive law and not a matter of practice and cannot be changed by the court.

Society News.—The Wood County Medical Society was addressed, November 11, at Marshfield, among others, by Dr. George L. McCormick, Marshfield, on "Recent Advances in Eye, Ear, Nose and Throat Treatment."——"Some Things the General Practitioner Should Know Regarding Nervous and Mental Diseases" was the subject of Dr. Arthur W. Rogers, Oconomowoc, before the November 13 meeting of the Marinette-Florence County Medical Society.——The University of Wisconsin Medical Society was addressed, November 21, by Dr. John Stanley Coulter, Chicago, on "Physical Therapy in General Practice."

GENERAL

Fraudulent Magazine Solicitor.—A man giving his name as D. L. Allerton and claiming to be a representative of Harper and Brothers is reported to be soliciting subscriptions to various publications from physicians in Iowa, Missouri and Nebraska. In answer to an inquiry, the firm of Harper and Brothers said that it did not employ agents and that the National Publishers Association was making an effort to apprehend the impostor.

Medical Bills in Congress.—S. J. Res. 213, introduced by Senator Smoot, Utah, and H. J. Res. 413, introduced by Representative Erk, Pennsylvania, propose to designate the first United States narcotic farm, to be established near Lexington, Ky., as the Stephen G. Porter Institute. S. 4784, introduced by Senator Bingham, Connecticut, and H. R. 14054, introduced by Representative Goss, Connecticut, propose to amend the National Prohibition Act, as supplemented, to permit physicians to prescribe malt liquors for medicinal purposes. H. R. 14268, introduced by Representative Rutherford, Georgia, proposes that officers, soldiers, sailors or marines who served in the military or naval forces of the Confederate states shall hereafter be admitted to the National Home for Disabled Volunteer Soldiers and to hospitals under the jurisdiction of the Veterans' Administration. H. R. 14275, introduced by Representative Glover, Arkansas, proposes to regulate the prescribing and use of waters from the Hot Springs Reservation at Hot Springs, Ark. H. R. 14693, introduced by Representative LaGuardia, New York, proposes to regulate the traffic in opium and narcotics, by regulating the shipments of such drugs to the United States from countries not signatories to the Hague Convention.

Another Child Welfare Foundation.—W. K. Kellogg of Battle Creek, Mich., has established a fund of $1,000,000 for immediate use with provision for additions that may reach $50,000,000, to be devoted to the aid of underprivileged children. The fund is to be known as the W. K. Kellogg Child Welfare Foundation. Children who are subnormal mentally or physically will receive scientific treatment to correct their defects or, if this is not possible, special training to minimize their handicaps. The work will be done largely in cooperation with schools. The activities will not be limited to Michigan, but aid will be extended wherever the need is apparent, subject to policies now being formulated. Dr. Stuart Pritchard, formerly of the Battle Creek Sanitarium staff, took up his duties as medical director of the foundation, December 1 (The Journal, December 6, p. 1751). Management of the foundation will be in the hands of a board, which includes, in addition to Dr. Pritchard: Wendell L. Smith, president and director; Eugene McKay, vice president and director; Lewis J. Brown, secretary-treasurer and director; Dr. Arthur C. Selmon and Earle Freeman, directors. During the past summer Mr. Kellogg established the Ann J. Kellogg School for Underprivileged Children at Battle Creek and a camp at Sherman Lake, where these children may spend summers under medical supervision.

Death Rate Decreases in 1929.—The U. S. Department of Commerce announced recently that 1,386,363 deaths occurred in 1929 in the registration area in continental United States, corresponding to a rate of 11.9 per thousand of population as compared with 12.1 in 1928. This area in 1929 comprised forty-six states, the District of Columbia, and nine cities in nonregistration states, with an estimated population, July 1, 1929, of 116,275,139, or 95.7 per cent of the total population; in 1928 the registration area included 95.3 per cent of the total population. The death rate from all causes per hundred thousand of population decreased from 1,207.1 in 1928 to 1,192.3 in 1929. This net decrease was almost entirely balanced by increases in influenza, diseases of the heart and meningococcus meningitis. Deaths from these three diseases alone caused 21.2 per cent of all deaths in 1928, and 22.7 per cent in 1929. Decreases among other important causes were for pneumonia (all forms), nephritis, congenital malformations and diseases of early infancy, tuberculosis (all forms), diarrhea and enteritis, diabetes mellitus, cancer and pellagra. Deaths from alcoholism decreased from a rate of 4.1 in 1928 to 3.7 in 1929. Deaths from accidental and unspecified external causes increased from 79.4 to 80.9. The types of accidents which showed the most noticeable increases were automobile accidents, excluding collisions with railroad trains and street cars (20.8 to 23.3) and accidental falls (14.1 to 14.6). A slight decrease was shown for deaths from drowning.

Report of Public Health Service.—Health conditions throughout the United States have been generally good during the past fiscal year, Surg. Gen. Hugh S. Cumming of the U. S. Public Health Service stated in his annual report to the present session of Congress. The death rate for pellagra has risen steadily from 2.5 per hundred thousand of population in 1924 to 5.5 in 1929. For five years there has also been a steady increase in the number of cases of meningococcus meningitis, but a slight decrease was noticed in the spring of 1930. Infantile paralysis was less prevalent than for several years during the calendar year 1929, but in the part of 1930 covered by the report a sharp increase was reported from several states. Smallpox has been increasing in the United States for three years. In forty-five states 34,685 cases of smallpox were reported in 1927, 38,114 in 1928 and 41,458 in 1929; 442 deaths occurred, although the disease was in most cases of a mild type. In the work of protecting the United States from importation of diseases from other countries, the report states that 20,645 vessels, 1,056,294 passengers and 1,380,241 seamen were inspected at domestic and insular ports and 1,211,796 alien passengers and 968,759 alien seamen were examined under the immigration law. Medical facilities for the care of seamen from merchant vessels were provided in 155 ports of continental United States and its insular and territorial possessions. The rapid development of intercontinental air travel has added a new phase to this work, the report points out. It is more necessary than ever to keep in touch with disease conditions throughout the world. Important events of the year were the change of the name of the Hygienic Laboratory to the National Institute of Health, with provision for acceptance of philanthropic gifts to finance research, and the creation of a division of mental hygiene, which assumed supervision of medical service in federal penal and corrective institutions. Congress also granted authority to the service for investigation of the abusive use of narcotics and the quantities necessary to supply the legal requirements of physicians in the United States. The personnel of the service in June, 1930, consisted of 1,476 medical officers and persons of other scientific ratings and 3,416 general and technical employees.

Maternal Mortality in the Registration Area.—The U. S. Department of Commerce announces that for the birth registration area the mortality from puerperal causes (7.0 per thousand live births) in 1929 was five tenths higher than the rate (6.5) for 1927, the last year for which the summary was published. The report says: "Confining the discussion to only three groups, namely, 'all puerperal causes,' 'puerperal septicemia' and 'other puerperal causes,' it will be noted that of the forty-six states for which data are available for 1929, South Carolina had the highest mortality rate (11.4), with Alabama and Louisiana next in order (each 9.9), Florida (9.5) and Georgia (9.3)." All the states with excessively high rates have large proportions of Negro populations. The states with high rates from puerperal septicemia are Montana (4.2), Colorado (4.0), New Mexico (3.9) and Arizona (3.8), all with vast rural areas sparsely settled, where hospital facilities and skilled medical care are difficult to procure. "Accidents of pregnancy" had a rate of only 0.7 for the entire registration area; puerperal hemorrhage and other accidents of labor, a rate of 1.6; and puerperal albuminuria and convulsions, 1.8, while the rates in the states for the three causes, respectively, were highest for Vermont (1.3), Delaware (3.0) and South Carolina (4.7). Heretofore the total number of deaths from these three causes has been listed under "other puerperal causes." Of the cities of 100,000 population in 1920, the highest rate for puerperal causes was for Memphis (16.0), followed by Nashville (14.7) and Birmingham (14.4). For accidents of pregnancy and for puerperal hemorrhage and other accidents of labor, Memphis again led with respective rates of 2.3 and 4.3 per thousand live births, while for puerperal albuminuria and convulsions, New Orleans had the highest rate (4.4). The city with the highest rate for puerperal septicemia was Nashville (9.0), followed by Memphis (6.1) and Akron and Birmingham (each 5.7). Cities that reached 100,000 population at the census of 1930 are included in the table and for these the highest rate (14.1) for all puerperal causes was for Jacksonville, Fla. The highest rate was that of Jacksonville, Fla. (2.7), for accidents of pregnancy; for puerperal hemorrhage and other accidents of labor Chattanooga was highest with a rate of 3.3; for puerperal septicemia Peoria had the highest rate, 8.9; Knoxville had the highest rate (4.0) from puerperal albuminuria and convulsions, and Somerville had the highest rate (1.2) for other puerperal causes.

An All-India Medical Council

The withdrawal of recognition of Indian medical degrees by the general medical council because of the refusal of Indian universities to allow inspection of their examinations was reported in The Journal, April 12, page 1156. The holding of an all-India conference for the maintenance of proper standards in provincial institutions for medical education has also been reported (August 9, p. 423). This conference of provincial and university representatives considered the creation of an all-India medical council for the purpose of maintaining a uniform standard of qualifications for the graduates of Indian universities and decided that the necessary steps should be taken without delay. The general medical council has expressed, by its president, Sir Donald Macalister, satisfaction that a solution of the vexed question of Indian medical standards, applicable to the whole of British India, should be practically envisaged by the government of India and that the responsibility for maintaining these standards, especially in relation to their extra-Indian aspects, should be assumed by a central Indian body. The council counts with confidence on the speedy establishment of a central board for India comparable with the medical boards or councils of other parts of the empire, to which it can refer for authoritative information on all questions of qualifications and standards. The council has received communications from India suggesting that, pending the establishment of the all-India Council, the degrees granted by the universities of Bombay and Rangoon should be recognized, but it has come to the conclusion that this would not be expedient or, indeed, just until the question can be dealt with as a whole, under conditions that would justify the council's guarantee of their sufficiency.

Experience of Birth Control Clinics

A meeting of medical officers of thirteen birth control clinics, who brought answers to a questionnaire previously circulated, relating to the failure of contraceptive methods, pathologic conditions, and hemorrhages observed in patients who had followed contraceptive methods for six months or more, was held in London. The information obtained was based on 6,322 cases. Among these there were 685 failures to prevent pregnancy, but of these only 95 were unaccountable; i. e., failure occurred though the prescribed technic had been properly carried out. The remaining 590 failures were traced to causes such as incomplete following of instructions, lapses from use of the method, deterioration of or faulty appliance, or other causes. In addition there was a group of 267 women who found the method impracticable for various reasons, such as esthetic dislike or discomfort to themselves or their husbands. An important observation was the entire absence of harmful results from following the instructions. The one case of pathologic effects occurred in a woman who wore the pessary continuously day and night whether there was any need or not. Only fifty complaints had been made by husbands. They mainly concerned the feeling of the anterior rim of the pessary and irritation of the penis by the lactic acid.

Accidents in Aviation

In the house of commons the undersecretary of state for air said, in reply to a question, that in the royal air force the number of deaths due to flying this year was sixty-two, an increase over last year's figure but practically the average for the same period in the preceding five years, when much less flying was done. The important point was the proportion of fatal accidents to the amount of flying done. For the period January-October, 1930, this is considerably lower than for any period from 1921 onward. A downward movement had thus been maintained, though not at a uniform rate. Of the sixty-two persons killed this year, thirty-five were in aircraft not fitted with slots or with slots not in operation, while fifty-four were supplied with parachutes. As regards safety devices, constant attention was given to the whole subject of the best means of improving the safety of flying and to the development of any devices that will do this. As a result there had been a progressive increase in the safety of flying.

Dame Mary Scharlieb is Dead

The death of Dame Mary Scharlieb, D.B.E., LL.D., M.D., M.S., at an advanced age removes a remarkable woman who entered the profession in middle life from humanitarian motives and became a skilful surgeon and the leader of her sex in the medical sphere. Mary Ann Suncomb Bird was born in 1845 near London. In 1865 she married a barrister, Mr. Scharlieb, and soon afterward accompanied him to Madras, where he practiced. She bore three children and helped her husband in the publication of law journals. She learned of the suffering of Hindu and Mohammedan women in childbirth because of the purdah system, which prevented aid from medical men. She was so affected that she determined to assist them by becoming a nurse at the lying-in hospital in Madras. She soon found that this was not enough and she entered with three other women the Madras Medical College, graduating in 1878. She went to England for further instruction, joining the London School of Medicine for Women, and in 1882 took the M.B. degree of the University of London with honors. She also attended a postgraduate course at Vienna. Returning to India in 1883, she was appointed lecturer on midwifery and gynecology at the Madras Medical College and accomplished a long cherished scheme to found a hospital for women. By 1887 the work had so told on her health that she had to return to England. In London she was appointed surgeon to the New Hospital for Women and subsequently was elected gynecologist to the Royal Free Hospital, being the first woman to hold a position on the visiting staff of a general hospital. She carried on a large consulting practice. She contributed the article on "Innocent Tumors of the Uterus" to the Encyclopaedia Medica and wrote on such subjects as "Welfare of the Expectant Mother," "How to Enlighten Children," and "Straight Talks to Women."

PARIS

Nov. 19, 1930.

The Congress of Otorhinolaryngology

The French Congress of Otorhinolaryngology met recently at Paris, at the Faculté de médecine, under the chairmanship of Dr. Caboche. The session was devoted to research on infection of the tonsils. The first official paper, presented by Worms and Le Mée, dealt with the problem of tonsillar foci viewed as the source of secondary infection. Acute articular rheumatism and chronic infectious rheumatism, bronchopulmonary disorders in children, and even appendicitis, may be the consequences of an infection due to a latent tonsillar focus, not to speak of possibly mycoses, tuberculosis and even cancer. The most interesting feature of the paper was Dr. Le Mée's description of the method he employs to discover experimentally the latent foci—what he terms "the tonsillar test." In applying massage, cupping or diathermy to the tonsil, a marked leukopenia is often observed, determined by the enumeration of the leukocytes in the blood before and after the maneuver—at the end of a quarter of an hour, an hour and a half and three hours and a half after the latter. The conclusion is that tonsillectomy is indicated whenever infectious disorders can be proved to be associated with a latent tonsillar focus. The second paper, that of Jacques of Nancy and J. Molinié of Marseilles, took up the indications and the technic of tonsillectomy; their conclusion is frankly in favor of total extra-capsular tonsillectomy. The nature of the discussion that followed revealed the advocates of total tonsillectomy and those who regard the tonsil as a useful organ that cannot be removed, other than partially, without doing damage to the organism. The most frank defender of the latter opinion was Professor Moure of Bordeaux, who stated that, thus far, his patients who had been treated according to the French method were in good health. A number of nonofficial communications were presented. Mr. Rendu of Lyons declared that local anesthesia was perfectly applicable to children, in spite of opinions expressed to the contrary. Mr. Dandin-Clavaud of Dunkirk recommended a procedure for the evacuation of the tonsils after electrocoagulation. Mr. Proby of Lyons spoke in favor of the Sluder-Ballenger method of tonsillectomy. Rebattu and Charachon of Lyons gave the results of their research on the bacteriology of the tonsil. Professor Canestro of Gênes discussed the value of periarterial sympathectomy in the treatment of pain in tuberculous laryngitis. During the congress, Dr. Chevalier Jackson of Philadelphia gave a lecture on esophagoscopy and bronchoscopy. In connection with the congress, a commemorative bust of Dr. Lermoyez was set up in the Hôpital St. Antoine, in the service that he founded and of which he was for a long time the director. The officers elected for the ensuing year were: president, Dr. Gault, Dijon; vice president, Dr. Hautant, Paris. The chief topic on the program will be: "The Indications and the Technic of Bronchoscopy." The official paper will be presented by André Bloch and Soulas.

International Congress of Orthopedic Surgery

A new international association, founded last year, held recently in Paris its first session. The first International Congress of Orthopedic Surgery convened under the chairmanship of Sir Robert Jones of Liverpool, assisted by Mr. Gocht of Berlin and Mr. Putti of Bologna. Twelve countries sent delegates. The first topic was the "Treatment of Congenital Luxation of the Hip After the Age of Fifteen" (papers by Professor Kreuz of Berlin, Dr. Dickson of Kansas City, Mr. H. A. T. Fairbanks of London, and Professor Putti). The second topic on the program was "Wrist Fracture" (papers by Dr. Albert Mouchet of Paris and Dr. Murk Jansen). Professors Ombrédanne and Mathieu performed several operations. The next meeting of the society will be held at London in 1933. The elected officers are: Mr. Nové-Josserand of Lyons, president; Mr. Murk Jansen, Leyden, vice president; Mr. Delchef of Brussels, general secretary; Mr. Maffei of Brussels, treasurer. The chief topic on the program will be "The Articular Mechanism in the Treatment of Coxalgia."

The International Professional Association of Physicians

The season of congresses, which comprised the month of October and part of the month of November, has come to a close in Paris. One of the last conventions was that of the general council of the Association professionnelle internationale des médecins. The previous session was held in Berlin. The fifth assembly was held in Paris in October, in the Hôtel de la confédération des syndicats médicaux, under the chairmanship of Dr. Rystedt, national correspondent of Sweden, assisted by the general secretary of the association, Dr. F. Decourt, national correspondent for France. Of the twenty-nine countries that are adherents of the association, seventeen were represented by their national correspondents, all of them presidents or secretaries of their national professional group; these were: Austria, Belgium, Bulgaria, Denmark, Danzig, France, Germany, Great Britain, Hungary, Jugoslavia, Latvia, Luxemburg, Netherlands, Norway, Poland, Sweden and Switzerland. The chief topics on the program were: "Organization of the Antituberculosis Crusade in the Various Countries," Dr. Decourt, France; "Representation of the Medical Profession in Governmental and Regional Organizations," Dr. Cox, Great Britain; "Insurance and Charitable Aid in the Medical Profession for the Physician and His Family," Dr. Schaeftgen (Luxemburg). In addition, the representatives of each country gave an account of the present state of health insurance in their own country. Dr. Decourt then discussed the question of the practical collaboration of the Association professionnelle internationale des médecins with the Confédération internationale des travailleurs intellectuels. Following the presentation of the subject by Mr. Gallie, general secretary of the confederation, the collaboration was unanimously agreed on. The assembly decided that the inquiries of the association for 1931 shall deal with the following two questions: "Health Insurance in 1931 in the Various Countries"; "The Organization of the Crusade Against Venereal Disease in the Various Countries." The next session of the general council of the association will be held in Budapest in 1931, under the chairmanship of Dr. Narbeshuber (Austria).

Diplomas Issued by the Faculties of Medicine

During the school year ended last July, the faculties of medicine of France issued doctor diplomas in medicine to the number of 1,172, the distribution of which among the several faculties is as follows:

Faculties of Medicine	Government Diplomas	University Diplomas	Total
Algiers	23	...	23
Beirut (Syria)	18	...	18
Bordeaux	151	5	156
Lille	50	1	51
Lyons	128	10	138
Marseilles	3	...	3
Montpellier	72	17	89
Nancy	39	4	43
Paris	477	71	548
Strasbourg	35	8	43
Toulouse	56	4	60
	1,052	120	1,172

It is announced also that the number of new students enrolled in the Faculté de médecine has increased still further, in spite of the circular advocating retrenchment, sent by the medical syndicates to the administrations of the lycées, or secondary schools. In the Paris faculty of medicine there are, this year, 6,072 enrolled, 4,095 of whom are French and 1,977 are foreigners, or an increase of 96 Frenchmen and 221 foreigners over last year.

American Aid for Establishments in France

A delegation from the United States called recently on the prefect of the Seine and informed him of a gift of one million dollars made to the city of Paris for the erection of a clinic for the treatment of diseases of the mouth, teeth and throat, where children in the public schools will receive free treatment up to the age of 16. The establishment will resemble that erected in Rochester, N. Y. Similar institutions will be erected in Rome and in London.

The Hôpital Stell, founded at Rueil, near Paris, by Mr. Edward Tuck, has been greatly enlarged as the result of an additional large donation received from the founder. Until her death, Mrs. Edward Tuck devoted much of her time and energy to this hospital, which was originally a private institution but which her husband donated to the department of Seine-et-Oise, together with a perpetual income to assure its adequate functioning. With the aid of the new donation, the hospital has been able to double its bed capacity, which was previously twenty-seven. It is now supplied with the most modern equipment. The inauguration of the new pavilions was the occasion of an official ceremony, at which the prefect of the department presided.

A Rockefeller institute has recently been established at Montpellier for the study of undulant fever.

ITALY

(From Our Regular Correspondent)

Oct. 15, 1930.

International Conference on Tuberculosis

At the seventh International Conference on Tuberculosis, held in Oslo, Italy was represented by a delegation comprising Prof. Raffaele Paolucci of the University of Bari, chairman, and Senator Maragliano of Genoa and Professor Morelli, deputy, director of the Clinica di tisiologica in Rome.

VACCINATION AGAINST TUBERCULOSIS

Professor Maragliano, who presented an official paper on preventive vaccination against tuberculosis, affirmed that vaccination to protect man against infection with the Koch bacillus is possible, and that it was first accomplished in Italy thirty years ago. Numerous types of vaccine have been proposed but the two most used are the French B C G vaccine and the Italian vaccine consisting of killed bacilli. The B C G vaccine has been applied to more than 250,000 children and has given results that, for the time being at least, must be regarded as evidence of its immunizing potency. The untoward results observed recently in Germany do not justify adverse criticism of the vaccine itself. The Italian vaccine has been in use for many years and has given encouraging results, as regards both its immunizing potency and its absolute harmlessness. It is being used more and more extensively in Italy. It should be admitted that there are many different antituberculosis vaccines; one should not overemphasize one type.

Professor Calmette recognized the fact that to Maragliano belongs the merit of having conceived the idea of preventive vaccination against tuberculosis and for having put it into practical execution, but he insisted on the view that, in order to obtain an effective defense, the presence of living bacilli is needed.

In reply, Maragliano brought out that the B C G vaccine has a limited and short life when inoculated into the human organism and that, as a matter of fact, one is dealing finally, in this case as well, with killed bacilli.

THORACOPLASTY

Professor Carpi of Milan presented an official communication on thoracoplasty. The speaker explained the new conceptions of elective pulmonary collapse, which have made possible the application of simultaneous bilateral pneumothorax, and which in the field of surgery justify interventions of a less extensive nature, such as partial thoracoplasty, apicolysis and phrenicotomy. Professor Malan of Turin reported a series of thirty cases of tuberculosis in which he performed a thoracoplastic operation, at first by the Wilms method and later by the Sauerbruch method. In the first cases in which he operated, general anesthesia was, if only indirectly, a frequent cause of death; the use of local anesthesia led to better results. Thoracoplasty may be recommended to patients when, after a period of sanatorium treatment, pneumothorax is inapplicable or phrenicotomy is adjudged insufficient. Contraindications are found in a gradual improvement in general health, an evolutional exudative process, a heart lacking resistance, a focus of infection in the opposite lung, and visceral tuberculosis. Certain rebellious cases of hemoptysis constitute a frank indication for thoracoplasty. However, before one proceeds with this grave intervention, therapeutic pneumothorax should always be tried first.

The Medical Convention at Bari

Physicians of various regions of southern Italy held recently a convention at Bari. The chairman, Prof. Ermanno Fioretti, described to the conventionists the activities of the Sanità pubblica italiana and the nature of the principal improvements. The sanitary work has been notably decentralized in recent years and many duties have been transferred from the ministry to the provinces, such as the supervision of the laboratories of hygiene and prophylaxis, the antituberculosis services, the general administration of quinine, and the antirabies treatment. Special courses of treatment are given to build up a defense against avoidable infectious diseases. For the promotion of odontologic studies, a six-year course has been organized at the University of Rome. Insurance against tuberculosis is now required of all classes of workmen. It applies to more than eight million workmen. The number of tuberculous patients at present is about 80,000. The cost of sanatorium aid is $26,250,000, in addition to the annual expenditure of $15,750,000 for the army. For protection against cancer, diagnostic and therapeutic centers have been established. Also courses of practical instruction for a specialized medical personnel have been organized. Numerous other provisions have been made for the protection of public health. Professor Quarante of Bari asked that special insurance measures be created for the benefit of physicians who are serving in institutions that admit tuberculous patients. The next regional convention of physicians will be held at Venice, for the benefit of the health officers of the Tre Venezie.

Antidiphtheria Vaccination

The minister of the interior has issued instructions to the prefects providing for a more intense and better organized prophylactic action against diphtheria infection to take the form of vaccination with anatoxin. The public health service has pointed out that in certain provinces the number of children vaccinated is small, owing to insufficient publicity on the part of the health officers. Vaccination is not obligatory, but the need of it, in the opinion of the minister, should be brought to the attention of the public.

The New Public Health Institute in Rome

The erection of the new Istituto di sanità pubblica in Rome, in the vicinity of the Policlinico, by the Italian government, toward which the Rockefeller Foundation made a large contribution, was recently begun. The institute will be under the direct control of the public health service and will have functions entirely distinct from those of the university institutes of hygiene. Its chief purpose will be the creation of a school for the education and training of sanitary personnel; it will serve as an aid to the public health service in the country in general, in the provinces and in the communes. The present laboratories of the public health service and of the Scuola superiore di malariologia will be reorganized, with new equipment, and will be located in the new institute.

CAPE TOWN

Mentally Defective Persons in the Union of South Africa

The investigation of the incidence of mental defectiveness, initiated in 1915 by Dr. J. M. Moll of Pretoria, has been carried on with comparatively little enthusiasm, since his death, which robbed South Africa of an earnest investigator. Educated in the school of Winckler, whose first assistant he had been for many years, Moll came to this country ill with pulmonary phthisis. Like others, he found health in the uplands of the Karroo and accepted an assistantship at a government hospital for the insane, where for years he engaged in routine administrative work. In 1915 he started practice as a specialist in mental diseases at Johannesburg, and the Transvaal education department gave him a roving commission to investigate the extent of mental defectiveness in the schools. His first report, in 1917, showed that in the Transvaal schools there was an average of 0.8 per cent of mentally defective children, a percentage that agreed fairly closely with the average percentage of 1 in 300 which he made for the whole white population. Since Moll's death, from Bright's disease, in 1920, the tendency has been to entrust much of the work of determining mental values to psychologists, whose evaluations are often vitiated by obvious defects of a physical nature that could be demonstrated in the children examined. In one case a lay examiner recorded a proportion of 7.4 mentally defective children, but on further investigation it was found that 76 per cent of the children suffered from chronic malaria, had a high fatigue index, and were for the most part unilingual and did not understand the tests used. Similar mistakes are frequently made in testing natives. More recent investigations appear to show that the aboriginal Bantu has an average mental quotient not far inferior to that of the average South African of white parentage, and that the percentage of mental defectives in native schools is certainly not higher than it is in European schools. At present an investigation is being made into the mental quotients of poor white children, but the work is not being done by a team comprising a psychiatrist, a psychologist and a pediatrician, and the results will probably not be of greater value than those published more than ten years ago by Moll.

Public attention has been drawn to mental deficiency by the discussion of the advantages of sterilization of the unfit. There is increasing juvenile criminality in the Union, and in these days of financial depression many taxpayers believe that too much is being paid for prison and police service. For all that the proposal to introduce legislation, on the American model, to enable the manifestly antisocial and unfit human derelicts to be sterilized, has so far found little favor with the general public. At present such sterilization is a crime, and legal opinion is unanimous that even consent on the part of the patient cannot make it justifiable. The local Branch of the Medical Association of South Africa had a combined meeting with the bar at which this matter was discussed. There has been a strong movement to induce the government to support a bill to legalize sterilization under proper precautions, but it seems clear that public opinion is not ready for such a step.

Racial Admixtures

One of the most interesting investigations that have been made during the past few years in this country has been completed by a scientist who in the course of a busy practice as a pathologist and bacteriologist, who incidentally has to prepare his own culture mediums and do practically everything single handed in his private laboratory, finds time to devote attention to purely scientific questions. This is an investigation into the blood groups of the South African Dutch, undertaken by Dr. A. Pijper of Pretoria. His results have been published in the Proceedings of the Koninklijke Akademie van Wetenschappen te Amsterdam (**32,** number 9, 1929). Some time ago he published, in the Transactions of the Royal Society of South Africa (**18,** part 4) a preliminary investigation which showed that the aboriginal Bantu have a blood index slightly higher than that of the American Negro. The work of Henderson and Lewis (The Journal, Oct. 21, 1922, p. 1422) stimulated him to undertake similar research here. So far as the Bantu are concerned he found that their blood index was 1.3. Previous work by Harvey Pirie, who had examined a small number of mine natives, had given a slightly higher index, while Mueller, working with West African natives, and Bruynoghe and Walravens, working with Belgian Congo natives had all found a blood index below 0.9. These figures seem to establish the fact that the west African Negroes have an index below that now found in their descendants in America, whose index is given as 1.3, and that the South African Bantu has even a slightly higher index. Dr. Pijper remarks: "Apart from a few historical curiosities there is no evidence at all that there ever has been an infusion of white blood into the Bantu. . . . The Bantu are the only native race of Africa of which we know that it has such a curiously high index. . . . The current belief about the origin of the Bantu is that they are of Negro origin with perhaps a slight admixture of Hamitic blood. My figures of the distribution of the blood groups make such views untenable. Whatever may have been the exact index of this Hamitic blood, it will not have been much higher than 1.5. A large infusion of white blood with an index of at least 3 has only succeeded in raising the original Negro index of 0.8 to 1.3 in America. It is therefore inconceivable that a slight admixture of Hamitic blood with an index of about 1.5 would have raised the Negro index to 1.3. The facts definitely point the other way; the Bantu have to be looked upon as direct descendants of the Hamitic race, with perhaps a very slight admixture of Negro blood."

Dr. Pijper, working with 596 descendants of Dutch families, the ancestors of whom came into the country before 1795, found that the blood index among this group is lower than that of the English and Hollanders, approaches that of the French, and equals that of the population of Berlin. The distribution of the blood groups in the South African Dutch, he declares, is of the western European type. But that distribution as a whole differs widely from that of the Germans and makes the South African Dutch resemble much more the Hollanders and the French. He found a blood index of 2.9 in the selected group, with a rather low incidence of the A group and the B group incidence somewhat high.

BERLIN

Nov. 24, 1930.

The Infant Deaths in Lübeck

According to a recent announcement of the ministry of the interior, the investigations carried on by Prof. Ludwig Lange in the federal bureau of health have led to further results. The periodic fluctuations in the epidemiologic course of the cases have persisted. The total number of deaths to date is seventy-three, the last occurring November 4, after an interval of seven and a half weeks. The examination of the B C G cultures from Lübeck is about completed. Further research has confirmed that the B C G cultures implanted in Lübeck in firm culture mediums about the middle of March and during the second half of April, 1930, did not contain virulent tubercle bacilli. On the other hand, additional evidence has been secured to show that the culture of Deycke (implanted, April 17), which was derived from a guinea-pig inoculated with a supposedly pure B C G emulsion, was a culture of virulent human tubercle bacilli. Another culture, which was obtained from a guinea-pig inoculated with a further B C G emulsion (also supposed to be pure), showed likewise high virulence for guinea-pigs. The rabbit experiments are not yet completed. In the examination of the remnants of four different culture emulsions (vaccine material) used in Lübeck for the treatment of children and sent in to the federal bureau of health subsequent to the deaths of the first infants, the cultivation experiments with two of the vaccine remnants were negative. From the remnant of the third vaccine substance, which had been given out, February 26, a culture of tubercle bacilli highly virulent for guinea-pigs was grown. The experiments on rabbits are not yet completed. In the remnant of the fourth vaccine substance, given out at the end of April, only avirulent B C G bacilli and no virulent tubercle bacilli have been found. With the exception of two instances, cultures of human tubercle bacilli have been secured from portions of the organs of deceased infants obtained at necropsy and inoculated into guinea-pigs. One of the two exceptions concerned an infant who had died forty-seven days after the vaccination (but from another cause and not from progressive tuberculosis) and from whose organs a pure B C G culture had been grown, while the second exception was another infant who had died ninety-one days after the vaccination and from whose organs cultures were secured in which in all probability (the researches in this case are not quite completed) likewise B C G cultures were involved. Moreover, no evidence has yet been obtained for the view that the morbific and fatal effects of so large a portion of the vaccine material administered to infants in Lübeck were due to a biologic transformation of the B C G cultures employed there. The final report of the investigating committee will be placed in the hands of the federal health council some time in November.

Opinions on the Working Capacity of Man at the Age of Thirty-Five

In taking up the discussion of the question as to whether or not the working capacity of man is diminished on reaching age 35, the *Deutsches Volksblatt,* published in Stuttgart, cited opinions of economic experts, parliamentary representatives and medical men. Prof. Fritz Strassmann of Berlin expressed himself as follows: "During my nearly forty years of activity as a medicolegalist, I have had occasion to issue many certificates concerning earning capacity, and my observations during that period do not lend the slightest support to the view that the working capacity of man undergoes a diminution by the time he reaches age 35." Dr. Grotjahn, occupant of a chair in social hygiene, gave this opinion: "That the physical capacity of a working human being on reaching age 35 is diminished to such an extent as to lessen his occupational fitness must be denied from both the medical and the hygienic point of view. There are few employments, such, for example, as that of the hard-coal miner, who works by artificial light and under the most disagreeable conditions, of which that might possibly be said. But even the coal miner does not usually begin to show a reduction of his physical capacity until about ten years later than the age mentioned. In the case of employees as a class, if they are in normal health, there is no reduction of physical capacity before the age of 60 is reached. The custom of many industrial establishments and commercial houses of giving absolute preference to young persons in selecting new employees is a regrettable lack of insight."

The Therapeutic Advantages of Seaside Resorts

At the session of the Deutsche Gesellschaft für Meeresheilkunde, which was held in Westerland auf Sylt, Miethke of Kiel referred in his paper to the fact that not only the milk of animals but also human milk, in the North Frisian Islands and on the coasts of the North and the Baltic seas, contain a much larger amount of iodine than in the regions of the interior, the excess amounting sometimes to 200 per cent of the normal amount. The drinking water likewise shows in places near the sea a higher iodine content. An exceptionally high percentage of iodine is found in the snow of the North Frisian Islands. In sea climates it is likely that the iodine content is therapeutically an important factor. Peat and moor in the vicinity of the coast contain large quantities of iodine, though the sands of the sea have very little. In regions near the sea, the eliminations of the kidneys and of the skin have been found to contain larger quantities of iodine than are found in the interior. These observations are important for the regional consideration of thyreotoxicoses.

Professor St. Engel of Dortmund spoke on "Maritime Medicine in Relation to the Diseases of Young Children." In the past there has been a tendency to neglect young children in connection with considerations pertaining to balneology. Infants, it is true, react slowly to sea climate. If young children are vasolabile or neurotic, their reactions in a maritime climate are unfavorable; otherwise they are good. Not many observations, however, have been made, for the reason that too few young children are sent to the seashore. The conditions of exudative diathesis in young children are best adapted for maritime treatment. In infancy exudative diathesis expresses itself more by its inflammatory nature; in young children more by its lymphatic manifestations, and in older children rather by its neurotic symptoms. Maritime treatment should, however, extend over a considerable period. Of children with rachitis, those who show a tendency to bronchial catarrh are most likely to receive benefit from a sojourn at the seaside. Children with asthma are benefited by climatic treatment at the seaside. The most important disease in young children in which seaside treatment is beneficial is tuberculosis, which expresses itself in the form of tuberculosis of the bronchial glands, meningitis and miliary tuberculosis. There is no specific treatment for these forms of tuberculosis, but the sea-bath treatment shows good results. It is not difficult to discover whether or not a child is tuberculous, if the Pirquet procedure is employed; it is, however, difficult to ascertain which cases are active, especially as the roentgenologic diagnosis and the erythrocyte sedimentatation test cannot be depended on.

Professor van der Reis of Danzig spoke on "Maritime Medicine and the Diseases of Advanced Age." Sea climates in their effects may be classed among the nonspecific remedies that produce a changed reactivity and are of great therapeutic value. The customary classification does not make sufficient allowances for the wide therapeutic differences between the climate that characterizes the beach, the dunes that lie back of the beach and the woods that border on the sea. Within a narrow area there is thus a transition from a stimulative climate to a relatively unstimulative one. The sojourn at the seaside acts through an ensemble of effects, including those of the pure atmosphere and the sea-baths. The chief point of attack of the stimulative effects of a stay on the seashore is the skin, which, when influenced, acts on the whole organism. The physiologic effects include changes in the capillary reactions of the skin, an increase of oxygen consumption, influence exerted on the mineral metabolism, and action on the blood and the circulatory organs and the functioning of the respiratory tracts and digestive organs. The indications for seaside treatment in internal diseases comprise above all "common colds" and diseases of the respiratory organs. A precondition is a careful selection of cases and precise observation of the susceptibility to stimulation and the effects of stimulation. Secondary anemias are favorably influenced by the seaside climate but pernicious anemia is not favorably affected. Heart patients may go to the seashore only in a compensated stage; the same rule applies to arteriosclerosis and high blood pressure. The assertion that neurotic patients must never go to the seaside is unfounded; but a careful selection of cases is requisite. Especial value attaches to the treatment of subacute rheumatic disorders and the interval stage, at the seaside. There is an urgent need of the creation of more therapeutic institutions by the sea.

Dr. F. Kirchberg of Berlin discussed the subject of "Gymnastic Exercises at the Seaside." The results secured with various forms of sport and gymnastic exercises in connection with sea-baths are excellent. They apply more particularly to an improvement in respiration and to an expansion of the chest. The hardening effects of gymnastics in the nude, by the seaside, are stressed. The hardening process makes possible a sojourn by the sea during cold weather—under certain conditions, even in the middle of winter. Gymnastic exercises serve to strengthen the musculature, whereas lying on the beach promotes an ontake of fat.

Marriages

EDWARD J. VAN LIERE to Miss Alice Evelyn Hartley, both of Morgantown, W. Va., in Uniontown, Pa., November 10.

JOHN W. JAMES, Saginaw, Mich., to Miss Helen Loraine Collaton of Toronto, Ont., Canada, November 5.

FRED LORD VARNEY, Monson, Maine, to Miss Laura J. Best of West Baldwin, November 27.

LEROY GOODMAN to Miss Marie Mulvey, both of Yukon, Okla., November 9.

Deaths

William Bedford Craig, Denver; St. Louis Medical College, 1875; Bellevue Hospital Medical College, New York, 1876; member of the Colorado State Medical Society, and the American College of Surgeons; emeritus professor of surgery, University of Colorado School of Medicine; on the staffs of St. Luke's Hospital, St. Joseph's Hospital, Mercy Hospital, Presbyterian Hospital, Children's Hospital, St. Anthony's Hospital and the Denver General Hospital; aged 75; died, November 27.

Robert Courtenay Loving ⊕ Colonel, U. S. Army, retired, Philadelphia; Medico-Chirurgical College of Philadelphia, 1902; entered the army as an assistant surgeon in 1903 and was promoted through the various grades to that of lieutenant colonel in 1917; served during the World War; retired for disability in line of duty in 1922, with the rank of lieutenant colonel; promoted colonel retired, under the Act of June 21, 1930; aged 52; died, November 7.

John Welch Boyce ⊕ Pittsburgh; Western Pennsylvania Medical College, Pittsburgh, 1892; served during the World War; member of the American College of Physicians; aged 59; associate editor of the *Pittsburgh Medical Bulletin;* on the staffs of the Pittsburgh City Home and Hospitals, Mayview, Western Pennsylvania Hospital, Eye and Ear Hospital and the Southside Hospital, where he died, November 23, as the result of a gangrenous gallbladder.

Oliver Edward Janney, Baltimore; University of Maryland School of Medicine, Baltimore, 1881; Hahnemann Medical College of Philadelphia, 1882; member of the Medical and Chirurgical Faculty of Maryland; at one time professor of practice and clinical pediatrics in the Southern Homeopathic Medical College; formerly on the staff of the Southern Homeopathic Hospital; aged 74; died, November 17, of pneumonia.

Blair Dabney Taylor ⊕ Colonel, U. S. Army, retired, Atlanta, Ga.; University of Virginia Department of Medicine, Charlottesville, 1869; Medical Department of the University of the City of New York, 1870; entered the army as an assistant surgeon in 1875; advanced through the various grades to that of colonel in 1908; retired in 1911 at his own request after thirty years' service; aged 82; died, October 29.

Myron Everett Fisher ⊕ Delevan, N. Y.; University of Buffalo School of Medicine, 1894; served during the World War; formerly member of the state legislature; member of the county board of health; for many years health officer of Delevan and Yorkshire; aged 65; died, November 29, as the result of injuries received in an automobile accident.

Marie S. Schmidt ⊕ Sheridan, Ill.; Northwestern University Woman's Medical School, Chicago, 1900; at one time clinical assistant in gynecology, Rush Medical College, Chicago; formerly on the staff of the Mary Thompson Hospital, Chicago; aged 67; died, November 15, of heart disease.

George Swan Mooney, Yonkers, N. Y.; Medical Department of Columbia College, New York, 1895; member of the Medical Society of the State of New York and the American College of Surgeons; on the staff of St. Joseph's Hospital; aged 74; died, October 17, of heart disease.

Gove Saulsbury Harrington, New York; Hahnemann Medical College and Hospital of Philadelphia, 1892; member of the American College of Surgeons; on the staffs of the Metropolitan and Broad Street hospitals; aged 63; died, November 25, of heart disease.

Edward A. Crokat, San Diego, Calif.; University of Manitoba Faculty of Medicine, Winnipeg, Man., Canada, 1894; member of the California Medical Association; aged 64; died, October 20, in the Quintard Hospital, of myocarditis and valvular heart disease.

Lurin Patrick Macklin, St. Louis; Washington University School of Medicine, St. Louis, 1909; member of the Missouri State Medical Association; member of the board of education; aged 43; died, October 15, of cerebral embolism and chronic endocarditis.

Frank Gerald Bishop, Ebensburg, Pa.; Temple University School of Medicine, Philadelphia, 1912; member of the Medical Society of the State of Pennsylvania; aged 60; died, November 7, in Johnstown, of an injury received in an automobile accident.

Harry Charles Johnson ⊕ Logansport, Ind.; Chicago Homeopathic Medical College, 1904; served during the World War; president and for many years member of the city board of health; aged 50; died, November 30, of pernicious anemia.

Joseph Martin Bennett, Providence, R. I.; University of Pennsylvania School of Medicine, Philadelphia, 1892; member of the Rhode Island Medical Society; formerly chairman of the state board of health; aged 66; died, in November.

Alexander R. Morton, Morton, Pa.; Jefferson Medical College of Philadelphia, 1886; past president of the Delaware County Medical Society; aged 67; died, November 8, in the Lankenau Hospital, Philadelphia, of gastric ulcer.

Cornelius S. Franckle, Millville, N. J.; College of Physicians and Surgeons, Baltimore, 1900; member of the Medical Society of New Jersey; aged 52; died, November 1, in the Jefferson Hospital, Philadelphia, of heart disease.

Allan Walker Urmson, New Castle, Pa.; Jefferson Medical College of Philadelphia, 1897; member of the Medical Society of the State of Pennsylvania; on the staff of the New Castle Hospital; aged 59; died, November 12.

Pugh Ulpian Brown, Troy, Ala.; Medical Department of the Tulane University of Louisiana, New Orleans, 1895; member of the Medical Association of the State of Alabama; aged 61; died, November 24, in a hospital at Mobile.

Mary Evelyn D'Aloret Johnston, Hamilton, Ont., Canada; University of Toronto Faculty of Medicine, Toronto, 1917; on the staff of the Mountain Sanatorium; aged 38; died, September 23, in the Toronto General Hospital.

James John Benson, West New York, N. J.; Baltimore University School of Medicine, 1899; member of the Medical Society of New Jersey; formerly member of the school board; aged 50; died, November 9, of heart disease.

August Elof Johnson ⊕ Minneapolis; Medical Department of Hamline University, Minneapolis, 1906; aged 61; died, October 19, on the S. S. *Europa* while returning to the United States from Sweden, of coronary sclerosis.

Thomas James McGovern, Braintree, Mass.; Tufts College Medical School, Boston, 1927; member of the Massachusetts Medical Society; on the staff of the Norfolk County Hospital; aged 34; died, November 13.

Herman Harvey Albers ⊕ Allenton, Wis.; Rush Medical College, Chicago, 1891; past president of the Washington-Ozaukee Counties Medical Society; aged 64; died suddenly, October 22, of cerebral hemorrhage.

Robert W. Alton, Portland, Mich.; University of Michigan Medical School, Ann Arbor, 1878; member of the Michigan State Medical Society; aged 76; died, November 9, in a hospital in Ann Arbor, of pneumonia.

George Otto Cosby, Elizabethtown, Ind.; Medical College of Ohio; Cincinnati, 1881; member of the Indiana State Medical Association; aged 77; died, November 9, in the Methodist Episcopal Hospital, Indianapolis.

Charles Wayman Wassmann, Bellaire, Ohio; Jefferson Medical College of Philadelphia, 1923; member of the Ohio State Medical Association; aged 31; died, October 30, in a sanatorium at Asheville, N. C.

Henry Fuller Curtis ⊕ Somerville, Mass.; Harvard University Medical School, Boston, 1891; member of the school board; on the staff of the Somerville Hospital; aged 66; died, October 29, in Framingham.

George Newton Mealy, Newton Falls, Ohio; Cleveland College of Physicians and Surgeons, Medical Department of the University of Wooster, 1882; aged 85; died suddenly, November 28, in Cleveland.

Daniel Leo McCormick, Newark, N. J.; Dartmouth Medical School, Hanover, N. H., 1896; member of the Medical Society of New Jersey; aged 56; was killed, November 27, in an automobile accident.

William Colin ⊕ New York; Medical Department of the University of the City of New York, 1898; on the staff of the Harlem Hospital; aged 54; died suddenly, November 22, of cerebral hemorrhage.

Joseph Armstrong Nevin ⊕ Jersey City, N. J.; New York Homeopathic Medical College and Hospital, 1906; medical inspector for the city public schools; aged 51; died, November 15, of heart disease.

Harold Francis Hope Eberts, Westmount, Que., Canada; McGill University Faculty of Medicine, Montreal, 1915; aged 40; was found dead in November, in his garage, of carbon monoxide poisoning.

Manley Alfred Davis, Gadsden, Ala.; Birmingham Medical College, 1911; member of the Medical Association of the

State of Alabama; aged 45; died, November 1, in a local hospital, of pneumonia.

Curtis Oliver Falk ⊕ Eureka, Calif.; Cooper Medical College, San Francisco, 1897; member of the American College of Surgeons; aged 54; died, October 19, in St. Joseph's Hospital, of sarcoma of the right femur and pneumonia.

Nathan C. Wallace, Dover, Pa.; Jefferson Medical College of Philadelphia, 1883; member of the Medical Society of the State of Pennsylvania; aged 75; died, October 12, of injuries received in an automobile accident.

Charles Francis Duchein, Baton Rouge, La.; University of Nashville (Tenn.) Medical Department, 1899; member of the Louisiana State Medical Society; aged 55; died, October 28, of pneumonia.

Walter Scott Brainerd, Haverhill, Mass.; University of Vermont College of Medicine, Burlington, 1883; member of the Massachusetts Medical Society; aged 71; died, November 13, of heart disease.

John B. Leffingwell, Bradenton, Fla.; St. Louis Medical College, 1880; member of the Florida Medical Association; formerly member of the county board of health; aged 76; died, November 19.

Maxwell J. Davis, Mansfield, Ohio; Ohio Medical University, Columbus, 1897; member of the Ohio State Medical Association; formerly city health commissioner; aged 67; died, November 26.

Robert O. Chambers, Centerton, Ark.; Homeopathic Medical College of Missouri, St. Louis, 1877; Barnes Medical College, St. Louis, 1894; aged 77; died, October 30, of chronic endocarditis.

Francis James Conroy ⊕ Grand Rapids, Mich.; University of Illinois College of Medicine, Chicago, 1910; served during the World War; aged 45; died, in November, of heart disease.

Frank Pierce Gardner ⊕ Seattle; Western Pennsylvania Medical College, Pittsburgh, 1896; served during the World War; aged 61; died, September 29, of cerebral hemorrhage.

George H. Boehmer ⊕ Sandusky, Ohio; Jefferson Medical College of Philadelphia, 1897; on the staff of the Good Samaritan Hospital; aged 58; died, November 27, of heart disease.

Robley Dunglison Blount ⊕ Valparaiso, Ind.; Medical College of Indiana, Indianapolis, 1889; served during the World War; aged 62; died suddenly, November 13, of heart disease.

John Allison Darrow, Erie, Pa.; Syracuse University School of Medicine, 1910; member of the Medical Society of the State of Pennsylvania; aged 48; died, July 22, of pneumonia.

Nelson Clifton Bissell, Dos Palos, Calif.; Cooper Medical College, San Francisco, 1904; aged 60; died, November 1, in the Letterman Hospital, San Francisco, of arteriosclerosis.

Elgin Kossuth Leake, Collierville, Tenn.; University of Virginia Department of Medicine, Charlottesville, 1872; for many years mayor of Collierville; aged 80; died, November 11.

Robert Marvin Bennett ⊕ Amarillo, Texas; Kentucky University Medical Department, Louisville, 1903; aged 56; died, October 10, in St. Luke's Hospital, Kansas City, Mo.

Henry F. Risch ⊕ Brooklyn; Bellevue Hospital Medical College, New York, 1879; aged 78; died, November 26, in the United Israel-Zion Hospital, of cerebral hemorrhage.

Frank Benjamin Golley ⊕ Milwaukee; University of Michigan Medical School, Ann Arbor, 1878; Bellevue Hospital Medical College, 1879; aged 74; died, November 30.

Francis Asbury Webb, Calvert, Ala.; Medical College of Alabama, Mobile, 1881; member of the Medical Association of the State of Alabama; aged 70; died, October 22.

John M. Stone, Laredo, Mo.; College of Physicians and Surgeons, Keokuk, Iowa, 1878; member of the Missouri State Medical Association; aged 81; died, September 18.

Francis Homer Blackman, Geneva, Ill.; Chicago Medical College, 1870; aged 84; died, November 8, at the Community Hospital, of myocarditis and acute prostatitis.

Franklin Pierce Boatner, Potts Camp, Miss.; University of Louisville (Ky.) School of Medicine, 1891; aged 78; died, September 20, in a hospital in New Albany.

Lyston H. D. Pierce, St. Petersburg, Fla.; Starling Medical College, Columbus, 1888; member of the Florida Medical Association; aged 69; died, November 4.

William Joseph Holland ⊕ Malden, Mass.; Georgetown University School of Medicine, Washington, D. C., 1903; aged 56; died, November 20, of pneumonia.

Nicholas J. Shields ⊕ San Luis Obispo, Calif.; Baltimore Medical College, 1898; on the staff of the Mountain View Hospital; aged 55; died, October 10.

Bert G. Jewett, Portland, Maine; Baltimore University School of Medicine, 1896; member of the Maine Medical Association; aged 57; died, September 4.

La Forest Almond Shattuck, Leesburg, Fla.; Eclectic Medical College of the City of New York, 1869; aged 84; died, July 6, in Ocala, of heart disease.

Theodore John Bertrand Meury, Saranac Lake, N. Y.; University and Bellevue Hospital Medical College, New York, 1912; aged 43; died, November 9.

Andrew Norris, Centerville, Tenn.; University of Nashville Medical Department, 1860; Confederate veteran; aged 92; died, November 10, in Nashville.

John Joseph O'Sullivan, New York; Medical Department of Columbia College, New York, 1894; aged 65; died suddenly, November 28, of heart disease.

Mary Leola Carrico ⊕ Danville, Ill.; Rush Medical College, Chicago, 1916; aged 37; was found dead in bed, November 16, of cerebral hemorrhage.

John E. Toole, Bainbridge, Ga.; College of Physicians and Surgeons, Baltimore, 1889; formerly mayor of Bainbridge; aged 62; died, in November.

Thomas Buchanan Sadler, Corsicana, Texas; Chattanooga (Tenn.) Medical College, 1895; aged 61; died, November 13, of heart disease.

P. C. Chadwick, Rockwood, Tenn.; Chattanooga Medical College, 1909; aged 44; died, October 13, of a self-inflicted wound of the throat.

George Crist Jenkins, Curwensville, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1879; aged 77; died in November.

Joseph Delahunt, Marathon, Iowa; University of Toronto Faculty of Medicine, Toronto, Ont., Canada, 1889; aged 70; died in November.

Henry S. Herman, Hagerstown, Md.; University of Maryland School of Medicine, Baltimore, 1876; aged 80; died, November 14.

William Royal Blackshear, Chireno, Texas; Beaumont Hospital Medical College, St. Louis, 1888; aged 80; died, November 5.

Joseph Edward Bundy, Sheldon, Ill.; College of Physicians and Surgeons, Keokuk, Iowa, 1883; aged 75; died, November 9.

Lonzo Virgle Smith ⊕ Alhambra, Calif.; Willamette University Medical Department, Salem, Ore., 1906; aged 49; died, October 30.

George Lake Blanchard ⊕ Los Angeles; Creighton University School of Medicine, Omaha, 1902; aged 53; died, August 2.

John D. Tieken ⊕ Piper City, Ill.; St. Louis Medical College, 1879; aged 76; died suddenly, November 19, of heart disease.

Clarence Christopher Duchscherer ⊕ Buffalo; University of Buffalo School of Medicine, 1903; aged 49; died, October 16.

Henry J. Von Gremp, Dixon, Mo.; Missouri Medical College, St. Louis, 1887; aged 67; was killed, August 15, by a train.

Ora Addison Chappelle ⊕ Elgin, Ill.; Rush Medical College, Chicago, 1892; also a dentist; aged 68; died, October 26.

Isaac Walter Bard, Cleveland; Cleveland Medical College, 1874; aged 77; died, November 5, in St. John's Hospital.

Matthew A. Layton, Detroit; Detroit College of Medicine, 1897; aged 67; died, October 31, of cerebral hemorrhage.

William Dallas Richards, Dayton, Ky.; Miami Medical College, Cincinnati, 1889; aged 80; died, November 13.

William T. Booth, Denison, Texas; Hospital College of Medicine, Louisville, 1875; aged 74; died, November 9.

John Page Tourner, Bloomington, Ind. (licensed, Indiana, 1897); aged 76; died, November 10, of heart disease.

Ward B. Short, Riverside, Calif.; Chicago Homeopathic Medical College, 1898; aged 62; died, October 13.

Isaiah T. Epps, La Grange, Ga.; Leonard Medical School, Raleigh, N. C., 1896; aged 62; died, October 30.

Carl E. Pfister, New York (licensed, New York, 1895); aged 70; died, October 31, in Berlin, Germany.

Bureau of Investigation

PHYSICIANS PROTECTIVE CASUALTY COMPANY

A Mutual Assessment Company Selling Accident and Sickness Insurance

During the past year, The Journal has received a number of inquiries relative to the Physicians Protective Casualty Company of Chicago. Especially have inquiries come in recently from Indiana, where this company seems to be rather actively engaged. Typical of the letters received are the following:

To the Editor:—I have been solicited by the Physicians Protective Casualty Company of Chicago for a noncancelable health and accident policy. I would appreciate any information you can give me relative to the company.
J. R. M., M.D., Chicago.

To the Editor:—I have held a policy from the Physicians Protective Casualty Company of Chicago for the last two years. In the earlier part of May, I claimed disability for the first time. A blank was mailed and was filed by the attending physician, as per request. I have written to them repeatedly, asking why they did not answer. Up to this minute my requests are ignored.
D. A., M.D., Brooklyn.

To the Editor:—I am writing an inquiry concerning the Physicians Protective Casualty Company of your city. Any information you can give me regarding them, as to their being an authentic company, will be greatly appreciated by me.
H. M. S., Indiana.

From such information as we have been able to get, it appears that the Physicians Protective Casualty Company was organized in October, 1928, and chartered under the laws of the State of Illinois. It claims to have complied with all the requirements in that state pertaining to mutual assessment companies under the legal reserve plan. The names of the officers and directors have been given as:

President: M. T. Rogers, M.D., Moline, Ill.
Secretary and Treasurer: J. W. Stamper, Chicago.
Vice-President: Carleton E. Gardner, osteopath and chiropractor, Macomb, Ill.
Directors: William E. Washburn, M.D., Kewanee, Ill.; D. Peter Wiens, M.D., Peoria, Ill.; Charles M. Atkinson, M.D., Havana, Ill.; William A. Steele, M.D., Havana, Ill.; William H. Braham, D.D.S., Canton, Ill.

In this connection, it is worth calling attention to the fact that M. T. Rogers, the president, is, apparently, Jennie Maude Thomas Rogers of Moline. We find Dr. Rogers' name in the files of the Bureau of Investigation as "Vice-President" of a so-called Medical and Legal Industrial Bureau of Moline, Ill. From letters received from physicians, it appears that this concern was brought into existence for the purpose of putting out an alleged directory of medical men that, according to the representatives of the Moline concern, would give such medical men as were listed therein preference in industrial insurance work and also act as a guide for insurance companies in selecting their examiners! Physicians, according to our correspondents, who wished to be listed in the proposed "directory" were to be charged sums ranging from $10 to $25. An Iowa physician, who wrote in regarding the scheme, stated that it occurred to him that this might be a "branch of business racketeering." Whether the Medical and Legal Industrial Bureau has ever collected any money from physicians and, if so, whether it has ever published a directory, we do not know. We have heard nothing about the scheme for more than a year and a half.

The moving spirit of the Physicians Protective Casualty Company seems to be the secretary and treasurer, J. W., or John W., or J. Wesley Stamper, who is not a physician but is said to have been formerly a book salesman.

Dr. Rogers and Mr. Stamper were president and treasurer, respectively, of an earlier concern known as the Medical Protective Association, Inc., which, according to a letter sent out over Stamper's name in April, 1927, sold a malpractice-defense service to the following group:

"Our membership principally comprises the following: Chiropractors, Osteopaths, Dentists, Physicians and Surgeons (not members of A. M. A.), Chiropodists, and etc."

This Medical Protective Association should not be confused with a high-grade and reputable insurance company of an almost exactly similar name that had been in existence for years before the Rogers-Stamper concern was organized. The *National Underwriter* for July 28, 1917, was authority for the statement that the certificate granted by the Secretary of State of Michigan to the Medical Protective Association had been canceled at the request of the State Insurance Department.

The Physicians Protective Casualty Company does not sell malpractice defense but accident and health insurance. The *Pocket Register of Accident Insurance* for 1930, published by the Spectator Company of New York and Chicago, shows the condition and business of American stock and mutual accident insurance companies throughout the United States. The issue dealing with the period ending January 1, 1930, states that the Physicians Protective Casualty Company of 105 West Adams Street, Chicago, paid for claims during 1929 only $2,522, while they used $24,871 for agents' commissions and expenses of management. This would indicate that during that period the company was paying out $10 for expenses to each $1 used for benefits!

A Brooklyn physician, whose letter to The Journal is the second of those published above, reported, as will be noted, that although he had held a policy in the Physicians Protective Casualty Company for some time, he was unable to get any attention paid to his claim for disability that he filed with the company last spring. His letters to the company were ignored. Finally, the Bureau of Investigation wrote to the Physicians Protective Casualty Company asking for an explanation of the concern's attitude in the case. The Bureau's letter was written November 4, 1930. On November 6, 1930, the doctor was sent a letter by the Physicians Protective Casualty Company with a check for $60, representing the amount claimed. The excuse given to the doctor was that, at the time his claim was filed, there was a complete change of personnel in the company's office, that his claim was marked paid, but, by oversight no check was issued. The oversight continued, apparently, from May, 1930, until November, 1930, when the Bureau of Investigation wrote to the company asking for an explanation and stating that The Journal expected to publish something on the subject in an early issue.

Those physicians who are prone to take out insurance mainly on the basis of low premium charges, should bear in mind that when dealing with a mutual assessment company, there is always the possibility of their being called on to make up deficits that may be incurred either through errors of management or heavy claims. Just what limits there are to the assessments that the Physicians Protective Casualty Company can call for is not altogether plain from the company's policy. The statement in the policy, "In case of emergency, this policy is subject to such premium payments as may be required by the company," would seem to imply that there is no fixed limit.

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

TESTS OF STERILITY

To the Editor:—Mrs. A. P. married at 21, became pregnant, and miscarried because of a severe fall. She became pregnant again and had a normal pregnancy, with normal delivery of a living child. There were two more pregnancies with miscarriages for no known cause. She was divorced from her husband, had an operation, so she was told, for the removal of the right tube and ovary, appendix, and also a ventral suspension. She married a second time, became violently ill two months after marriage, an Australian surgeon did an exploratory laparotomy on her, and told her that he found a four weeks' tubal pregnancy in the left tube He told her that he removed the mass, swabbed out the tube, and sewed her up without drainage. She made an uneventful recovery, and the surgeon told her that there was no reason why she should not become pregnant again. In fact, he gave her a signed statement to the effect that the tube was uninjured. This was four years ago, and there has as yet been no further pregnancy. Both the patient and her husband are most anxious to have children and want to know if there is any possibility of another pregnancy. The patient's menses are regular and painless She leads a normal life and is quite healthy. Is it possible to reopen the tube? If so, who is competent to do the operation?
M.D., Georgia.

Answer.—The operation on the only tube which this patient had does not necessarily imply obstruction of this tube and sterility. There are cases on record in which an ovum has been removed from the only tube a patient had and this has been followed by a pregnancy. In some instances the pregnancy subsequent to the operation again developed in the tube that was operated on, but in other instances the fertilized ova were implanted normally in the uterine cavity and full-term children were born. When an ovum is removed from a tube and the tube is left, there is a distinct danger of the recurrence of a pregnancy in this tube and this should be explained to the patient and her husband. This danger is most likely greater than the repetition of an ectopic gestation in the opposite tube in women who have both tubes.

In the present case, to determine whether or not the tube is patent, a Rubin tubal patency test should be performed. If the tube is found to be impermeable to gas, iodized oil should be injected and a roentgenogram taken to determine the site of the obstruction. It is assumed that bimanual examination reveals a normal condition other than the absence of the right tube and ovary. If abnormalities, especially evidences of inflammation, are found, the Rubin test should not be performed. In a fair proportion of cases, pregnancy follows the demonstration of tubal patency by the Rubin test. If an obstruction is found, a plastic operation on the tube may be performed. This can be done by any capable gynecologist, but the patient and her husband should be told that the chances for a uterine pregnancy are certainly no greater than one in five. If the tubal obstruction is due to sealing off of the tubal mucosa, the chances for a pregnancy are much less than in the cases in which the tube is closed by factors outside the tubal lumen.

SCARLET FEVER OR EXFOLIATIVE DERMATITIS

To the Editor:—A boy, aged 6, whom I saw on the third day of illness, had been taken ill with vomiting, diarrhea and fever. He had a rash of one day's duration, typical of scarlatina, a raspberry tongue, a reddened throat and palpable cervical glands. He had been treated with scarlet fever serum seventeen months before when scarlet fever had been diagnosed. In about eight hours he had developed a temperature of 106 F., clearing by the following morning, sixteen hours. The mother says that on several occasions he has developed a similar condition of the tongue and a rash, to subside in about a day with subsidence of the fever. The same symptoms occurred this time. Does this appear to be a simple diffuse erythema, or is it possible that the boy is a scarlet fever carrier, developing mild scarlet fever because of his previous serum treatment? Kindly omit name.

M.D., Connecticut.

Answer.—The administration of scarlet fever antitoxin, therapeutically, for the treatment of scarlet fever already developed in a patient, does not prevent the development of immunity to the disease. Second attacks of scarlet fever may occur whether or not the first attack is treated with antitoxin, but the frequently recurring rashes in this instance are not attacks of scarlet fever. If desquamation follows the erythematous eruption, it would suggest exfoliative dermatitis.

MINERAL OIL ABSORPTION OF VITAMINS

To the Editor:—I have been told that recent experiments with mineral oils show that these oils absorb and carry off the fat-soluble vitamins. So far, I have not been able to locate any published reports of these experiments and wonder whether you could perhaps throw some light on the subject for me.

Miss P. A. Clark, New York.

Answer.—The problem to which our correspondent refers was referred to in an editorial on "Some Recent Observations on Fat-soluble Vitamins" (The Journal, Aug. 27, 1927, p. 694). There have been only few experimental investigations dealing directly with the problem. These have been published as follows:

Burrows, M. T., and Farr, W. K.: *Proc. Soc. Exper. Biol. & Med.* **24:** 719 (April) 1927.
Dutcher, R. A.; Ely, J. O., and Honeywell, H. E.: *Proc. Soc. Exper. Biol. & Med.* **24:** 953 (June) 1927.
Ely, J. O.; Honeywell, H. E., and Dutcher, R. A.: *Pennsylvania State Coll. Agr. Exper. Sta. Bull.* 243, 5, 1929.
Hawk, P. B.; Levine, H.; Stucky, C. J., and Oser, B. L.: Abstract of paper read before the American Chemical Society, Minneapolis, 1929.
Moness, E., and Christiansen, W. G.: *J. Am. Pharm. A.* **18:** 997, 1929.

Indirect references to the subject will be found in the following papers:

Collison, D. L.; Hume, E. M.; Smedley-Maclean, I., and Smith, H. H.: *Biochem. J.* **23:** 637, 1929.
MacDonald, M. B.; Andes, E. C., and Briggs, F A.: *J. Home Econ.* **22:** 213, 1930.
Marcus, J. K.: British patent 289798, Chem. Abstr. **23:** 933, 1929.
Mellanby, John: *J. Physiol.* **64:** 33 (Dec. 29) 1927.
Moore, T.: *Biochem. J.* **23:** 1272, 1929.

The evidence is still somewhat unconvincing, so that further experimental investigation is urgently desired before any final pronouncements on this subject are justified.

TREATMENT OF ALCOHOLISM

To the Editor:—Is there any drug or other agent that will relieve one of an almost overpowering desire for alcohol? I have a patient who pleads with me for such a remedy. These attacks are periodic, but there remains always some desire. With the help of bromides and capsicum I have so far managed to tide him over. However, the situation is far from ideal. Any suggestions would be appreciated. Please omit name and town.

M.D., New Jersey.

Answer.—The solution of the alcoholic habit does not rest on drugs alone; they play the minor part in the treatment. Each alcoholic addict uses alcohol for a reason or cause that is sufficient to himself and the cure depends on the removal when possible of the internal and external causes for which the alcoholism is merely an expression.

The craving for narcotics is not purely a physical need; it is chiefly mental and if the physician can give his patient a mental "kick" that is bigger than the idea or desire for the alcohol he may be successful. It might be advisable to try the following:

Atropine sulphate..................	0.13 Gm.	(2 grains)
Strychnine sulphate................	0.5 Gm.	(8 grains)
Water............sufficient to make	90 cc.	(3 ounces)

One drop three times a day after meals, increasing one drop every twenty-four hours as follows:

First day: morning, 1 drop; noon, 1 drop; night, 1 drop
Second day: morning, 2 drops; noon, 1 drop; night, 1 drop
Third day: morning, 2 drops; noon, 2 drops; night, 1 drop
Fourth day: morning, 2 drops; noon, 2 drops; night, 2 drops
Fifth day: morning, 3 drops; noon, 2 drops; night, 2 drops

The dosage is increased to ten or more drops three times a day until symptoms of atropine poisoning appear; then it is reduced five drops and continued for three weeks more.

The patient should come to the office daily for observation for the first three weeks, and then two or three times a week. If during this time or later an acute desire to drink appears, 3 mg. (one-twentieth grain) of apomorphine should be administered hypodermically every three or four hours until the desire ceases.

SYPHILIS IN PUERPERAL PATIENT

To the Editor:—Two weeks ago an apparently healthy child was born in a local hospital from an apparently healthy mother. The cord Wassermann reaction was 3 + with noncholesterolized antigen and 4 + with cholesterolized antigen. The Wassermann reaction taken on the mother was 4 + with both antigens about a week after delivery. The mother is nursing the baby and both are apparently doing well. Please give the proper treatment for this case. How soon can mercury inunctions be used on the baby? Please omit name and address.

M.D., New York.

Answer.—A 4 plus Wassermann reaction obtained in a puerperal patient signifies syphilis in nearly every instance. A baby born of a syphilitic mother may nurse its own mother. Treatment of both mother and child should be begun soon after birth. The child may be given mercury rubs every second day and also intramuscular injections of neoarsphenamine or other arsenical preparations once a week for a few weeks. For the first few weeks the mother should be given iodide by mouth and intramuscular injections of bismuth, arsenic or mercury preparations. After she has been up and around for a while, intravenous arsenic therapy may be instituted. It is inadvisable to give intravenous therapy, especially arsenic, too soon after childbirth because puerperal women are more prone to have bad reactions from this therapy than are other individuals.

IMPORTANCE OF AIR VENT IN BATH ROOM FROM HYGIENIC POINT OF VIEW

To the Editor:—The city plumbing regulations demand a vent attached to the drain of sinks, bathtubs and toilets; this vent must run to the roof of the building and its purpose is to allow the escape of air and "sewer gas" from the drain pipes. Has it ever been shown that a vent is necessary from the health standpoint, provided the drain has a competent water trap? If a wash basin in a physician's office should be installed without a vent, and used occasionally for the disposal of urine, would it give rise to insanitary conditions or obnoxious odors? Please omit name.

M.D., New Jersey.

Answer.—There is no evidence that sewer gas is a definite health hazard causing any specific disease. It used to be stated that sore throats, diphtheria and typhoid might be spread in this way, but the evidence produced to support these claims is worthless. If continual living under obnoxious conditions directly affects the health, to that extent a vent can be regarded as a minor health factor. It is possible that plumbing installed without a vent might give rise to obnoxious odors. A vent is necessary not so much for the purpose of allowing the escape of sewer odors to the roof as to make it impossible for the "traps" that are standard parts of wash basins, bath tubs and water closets to be siphoned out to the point at which the water in such traps no longer seals them.

NEW NAMES FOR OLD UNACCEPTABLE PROPRIETARY PRODUCTS

To the Editor:—I have received the enclosed letter and literature from the Southwest Medical Supply Company regarding use of their products in the treatment of syphilis, rheumatism, gonorrhea and asthma. Kindly send me any information you have regarding these products: "Onolin," "Aritine," "Amazine" and "Lesol."

M.D., California.

Answer.—Those who noted a recent current comment in The Journal (The Horovitz Proteins and Lipoids Again, The Journal, Dec. 21, 1929, p. 1975) will recognize in the products named by our correspondent the ill concealed names of Gonolin, Arthritine, Asthmazine and Luesol. Here is a group of the various names under which, as pointed out in the comment, the Horovitz proteins and lipoids are marketed by various firms. The advertising circulars that are sent for one group are the same (except for the name of the product) as those sent for the other group, the genealogy of which has been traced from the original Horovitz mixtures, through the Merrell Proteogens, to the present products of the Lipoidal Laboratories, Inc. The advertising for each is a farrago of pseudoscience which will take in only those who have not learned to examine critically the evidence and methods by which more or less astute exploiters attempt to gain medical credence for secret and probably worthless preparations. It is no doubt only a question of time until the discredited Horovitz protein substances and lipoids will break out with new names and possibly a somewhat different line of pseudoscientific advertising copy. Said a famous Frenchman, "The more it changes, the more it is the same thing."

VITAMINS IN CANNED PRODUCTS

To the Editor:—I should like to have the opinion of your Committee on Foods as to the difference of value in vitamins between the following fresh and canned foods of the fall: tomatoes, beets and carrots. What is the value in vitamins of Carnation condensed cream, grapefruit juice, and Karo syrups?

Mrs. O. H. Googe, Atlanta, Ga.

Answer.—Tomatoes, beets, carrots and grapefruit, prepared by the so-called former open kettle process, lose considerable of the original vitamin values. This process, however, is now largely replaced by more modern methods which destroy little of vitamins A and B (complex) and even in larger measure permit preservation of the heat labile vitamin C. The vitamins of acid fruits, such as tomatoes, are especially well preserved in canning.

Condensed milks, as a whole, contain practically all the vitamin A and B content of the original milk. Vitamin C is in lessened amounts.

Karo syrups do not provide vitamins.

VITAMINS IN CANNED CITRUS FRUITS

To the Editor:—Can you tell me in what manner canned citrus fruits are preserved and whether they contain the vitamins of the fresh fruit?

S. A. Munford, M.D., Clifton Springs, N. Y.

Answer.—The only canned citrus fruit products that have been submitted to the Committee on Foods and accepted are Whitefield Genuine Orange Juice and Whitefield Genuine Grapefruit Juice. The announcement of acceptance of the Grapefruit product appears in The Journal, December 13.

The vitamin content of the original orange juice is almost completely preserved in the final product. This preservation is accomplished by low pasteurization temperatures and by processing in an atmosphere of carbon dioxide. The juice is packed under partial vacuum, which is maintained in the containers by special capping.

FLAT FEET

To the Editor:—Should a child at 16 months of age receive treatment for flat feet? This child was seen by me, August 6, and is normal. There are no signs of rickets, the knees are straight, the child walked at 13 months, but both inner malleoli come very near the floor. Would you advise any special treatment? Please do not publish name.

M.D., Iowa.

Answer.—The child probably has flat feet of a hereditary or familial type. This condition is more often found to be transmitted through the paternal side. Accessory scaphoids are often found in this type of condition. Treatment should be instituted immediately. This should include high laced shoes with round toes and rigid shanks. The heels should be longer and higher along the inner borders than on the outer. There should be a flexible inner support for the longitudinal arch. Longitudinal arch exercises should be given to increase the power of the supporting structures of the longitudinal arches. Massage in the corrected position may be beneficial. If this does not produce correction, repeated plaster casts should be applied; while these casts are being worn, the child should be allowed to walk.

PLURAL OF LEPTOSPIRA

To the Editor:—Will you state the plural of the word *Leptospira?* I have seen "leptospiras," "leptospirae," and "leptospira" used by different medical writers. Which is correct? Please omit name and address.

M.B., India.

Answer.—Certain words have English plurals when used as common nouns and Latin or Greek plurals when used in scientific names. For example:

English	Latin
amebas	*Amoebae dysenteriae*
ancylostomas	*Ancylostomata duodenalia*
spirochetes	*Spirochaetae pallidae*
tenias	*Taeniae saginatae*
uncinarias	*Uncinariae americanae*

Therefore it would be the usage of the American Medical Association press to use the form "leptospiras" or "*Leptospirae*" according to the context.

READING OF DIASTOLIC PRESSURE

To the Editor.—Will you please explain the causes of a diastolic pressure of 0 with a systolic 120? Please omit name.

M.D., Michigan.

Answer.—A diastolic pressure of zero may be experienced if the diastolic pressure is read at the complete disappearance of the sound. It is better to consider the diastolic pressure to be the reading found just at the beginning of the fourth phase; i. e., just as the sound begins to get more dull and begins to pass into the fifth phase, where the sound disappears altogether. In this way, readings of zero are more rarely experienced. A low diastolic pressure may occur in aortic insufficiency and with any condition in which there is a peripheral vasodilatation.

VITAMIN E

To the Editor:—Kindly inform me which products contain vitamin E that could be fed to infants.

Leslie Y. Katona, M.D., Flushing, N. Y.

Answer.—Vitamin E is a fat-soluble principle occurring in muscles, fat, pancreas, spleen, liver, heart, hypophysis, placenta and other structures of animals. It is less abundant in the viscera, including the liver, than in muscle. Heart, spleen, brain, kidney and testes contain little E, whereas muscle and fat *contain it in considerable amounts. Milk fat is a* poor source. Cod liver oil is notably lacking in E. The seeds and green leaves from plants are good sources. Even dried lettuce and peas contain it. This vitamin is present in corn, oats and especially in wheat. The germ or embryo of the wheat in particular is an abundant source.

CALCAREOUS DEPOSIT IN PARA-URETHRAL GLAND

To the Editor:—August 15, a woman, aged 44, the mother of fourteen children, consulted me about some bladder trouble. On examination I noted a small tumor about the size of a small marble to the right just below the urethral opening. On palpation the tumor felt as if it contained calculi. I opened the tumor and found 100 stones about the size of a grape seed. No connection with the bladder could be demonstrated. The stones were dry and no urinary odor was present. Please give me your opinion as to the source of the stones.

Harry H. Bolton, Jr., M.D., Pierce, W. Va.

Answer.—Deposits of calcareous material may occur anywhere in necrosing tissue. In the instance referred to, evidently the mucous lining of a para-urethral gland underwent necrobiosis as the result of some inflammatory process and the precipitation of the lime salts followed.

FOOT DROP

To the Editor:—I have a patient suffering from foot drop due to an injury to the knee, leg and ankle. Would there be any chance of this man's recovery of control of the foot if he underwent an operation?

J. R. Stringham, M.D., Cheboygan, Mich.

Answer.—*The injury is indefinite and should be stated* more specifically to warrant a complete reply. No matter what the cause, a foot drop can usually be corrected; this may be possible by nonoperative orthopedic treatment, but surely by operation.

Medical Education, Registration and Hospital Service

COMING EXAMINATIONS

Alabama: Montgomery, Jan. 12, 1931. Sec., Dr. J. N. Baker, 519 Dexter Ave., Montgomery, Ala.

Arizona: Phoenix, Jan. 6-7, 1931. Sec., Dr. H. P. Mills, 14 N. Central Ave., Phoenix, Ariz.

Colorado: Denver, Jan. 6, 1931. Sec., Dr. W. W. Williams, 224 State Capitol Bldg., Denver, Colo.

Dist. Columbia: Basic Science, probably Dec. 28, 1930. Regular, Jan. 12, 1931. Washington, D. C. Sec., Dr. W. C. Fowler, District Bldg., Washington, D. C.

Illinois: Chicago, Jan. 13-15, 1931. Supt., Mr. P. B. Johnson, Dept. of Registration and Education, Springfield, Ill.

Minnesota: Minneapolis, Jan. 6-7, 1931. Basic Science. Sec., Dr. E. T. Bell, 110 Anatomy Bldg., Minneapolis, Minn. Regular, Minneapolis, Jan. 20-22, 1931. Sec., Dr. E. J. Engberg, 524 Lowry Bldg., Minneapolis, Minn.

New York: Albany, New York City, Syracuse and Buffalo, Jan. 26-29, 1931. Chief, Mr. H. J. Hamilton, Albany, N. Y.

North Dakota: Grand Forks, Jan. 6-9, 1931. Sec., Dr. G. N. Williamson, Grand Forks, N. D.

Washington: Seattle, Basic Science, Jan. 8-9, 1931. Regular, Jan. 12-13, 1931. Dir., Mr. Charles Maybury, Olympia, Wash

Wisconsin: Madison, Jan. 13-15, 1931. Sec., Dr. R. E. Flynn, 315 State Bank Bldg., La Crosse, Wis.

Wyoming: Cheyenne, Feb. 2, 1931. Sec., Dr. W. H. Hassed. Capitol Bldg., Cheyenne, Wyo.

Porto Rico September Examination

Dr. Diego A. Biascoechea, secretary of the Board of Medical Examiners of Porto Rico, reports the written and practical examination held at San Juan, Sept. 2-13, 1930. The examination covered 16 subjects and included 75 questions. An average of 75 per cent was required to pass. Ten candidates were examined, 9 of whom passed and 1 failed. The following colleges were represented:

College PASSED	Year Grad.	Per Cent
Georgetown University School of Medicine	(1929)	86.7
George Washington University Medical School	(1930)	87.6
University of Georgia Medical Department	(1929)	78
University of Maryland School of Medicine	(1930)	84.8
Boston University School of Medicine	(1930)	81.8
Harvard University Medical School	(1929)	84.6
Columbia University College of Phys. and Surgs	(1930)	87.3
Jefferson Medical College	(1924)	85.1
University of Lausanne Faculty of Medicine	(1928)	81.3*

College FAILED	Year Grad.	Per Cent
Chicago College of Medicine and Surgery	(1916)	51 †

* Verification of graduation in process.

† This candidate took the examination the first day, September 2, but did not reappear for the completion of the examination. He obtained a grade of 51 per cent in the first subject, Anatomy.

New Jersey June Examination

Dr. James McGuire, secretary of the Board of Medical Examiners of New Jersey, reports the written examination held at Trenton, June 17 and 18, 1930. The examination covered 9 subjects and included 90 questions. An average of 75 per cent was required to pass. Eighty-six candidates were examined, 83 of whom passed and 3 failed; 1 withdrew. The following colleges were represented:

College PASSED	Year Grad.	Per Cent
Yale University School of Medicine	(1928) 80.5, (1929)	81.5
Georgetown University School of Med.	(1928) 80.8, (1929)	78.6, 79.4, 79.5, 79.9, 80, 80, 81.3, 82.1, 83.2, 85.7, 86.7
George Washington University Medical School	(1927)	82.3, (1929) 82.9, 83.7, 88.2, 89
University of Maryland School of Medicine	(1929) 82.8, 83.6,	85.7
Boston University School of Medicine	(1929)	80.5
Tufts College Medical School	(1929) 87.7, 88.8,	89.2

Book Notices

Illustrated Primer on Fractures. Prepared by the Cooperative Committee on Fractures under Auspices of Section on Surgery, General and Abdominal, and Section on Orthopedic Surgery in Cooperation with Department of Scientific Exhibit of the American Medical Association. Cloth. Price, $1. Pp. 55, with illustrations. Chicago: American Medical Association, 1930.

This consists of a series of line drawings representing certain standard procedures in fracture work, with the high points in each procedure represented by signs on the walls of the room in which the procedure is being carried out. Following each drawing is a concise text. The drawings are simple and clear and give definite ideas of the important points in each procedure. Though variations in fractures and roentgenograms are not considered, a few anatomic diagrams are introduced for each procedure and they are illuminating to the text. Most of the book goes straight to the point of how to do it, but a few timely warnings are given. Only the simplest methods of treatment with plaster and well known standard splints are shown. Methods of traction, transportation, reduction and the prevention of deformities are gone into simply and effectively. For the student and for the general practitioner who must treat an occasional fracture, the book is a valuable contribution. The diagrams are not beautiful but they are extremely clear. The book follows the demonstrations devised by the Fracture Committee of the American Medical Association and is practically a reproduction of these, necessarily lacking one important phase—the possibility of getting additional information from the demonstrator in charge of the booth. The book fulfils its purpose.

Ergebnisse der Sozialen Hygiene und Gesundheitsfürsorge. Band II. Herausgegeben von Professor Dr. A. Grotjahn, o. Professor der Sozialen Hygiene an der Universität Berlin, Professor Dr. L. Langstein, a. o. Professor der Kinderheilkunde an der Universität Berlin, und Professor Dr. F. Rott, Privatdozent für Soziale Hygiene an der Universität Berlin. Paper. Price, 36 marks. Pp. 497, with 27 illustrations. Leipzig: Georg Thieme, 1930.

The second volume of this useful publication is worthy of its predecessors. It contains comprehensive discussions of such subjects as the relative influence of social environment and inheritance, the methods and value of periodic health examinations, the feeding and recreative facilities of school children, the epidemiology of poliomyelitis, tuberculosis mortality in England and Wales, the new German mortality tables, the specific male mortality as a means of measuring the mortality due to alcohol, and other topics of more or less general interest. As has been noted before in reviewing recent German summaries, some of the articles suffer because the authors have not, apparently, had access to other data than those in the German language. In the present volume this limited outlook is especially noticeable in the discussion of poliomyelitis, in which the extensive and fundamental work of Aycock and others in the United States receives scant consideration. The article on periodic health examinations, on the other hand, draws freely on the rich American data. Although of varying value for the American reader, nearly all the articles contain information and reveal points of view that will be of assistance to the reader able to supplement his knowledge from other sources.

Nervous Indigestion. By Walter C. Alvarez, M.D., Associate Professor of Medicine, University of Minnesota (The Mayo Foundation). Cloth. Price, $3.75. Pp. 297. New York: Paul B. Hoeber, Inc., 1930.

This monograph is the outgrowth of the author's contributions to medical periodic literature. It provides not only his own contributions in the field of research but also his clinical study. Indeed, the clinical phase represents at least half of the complete work. Each of the chapters is preceded by quotations from secular literature. Dr. Alvarez considers relationship of emotion to the digestive tract, types of indigestion, hints in regard to the taking of a history, the handling of a patient, the treatment of nervous indigestion, and some practical points about the physiology and innervation of the digestive tract. He concludes his book with a bibliography, and a chapter of suggestions for further reading. As is usual with volumes issuing from the Hoeber press, this book is pleasing from a typographic point of view, the type column makes for easy readability, the type itself is large, the side and center heads split up the text, and the text itself has in it the literary quality that one has come to associate with the Alvarez contributions. The author presents his cases so graphically that his language makes them visible. He is by way of being a practical psychologist who gets his results promptly rather than by the forever enduring methods of the modern psychoanalyst. It is doubtful whether patients with nervous indigestion can be cured of their complaints by reading books, but it seems likely that this volume would do much for such a patient; certainly the physician will want to know as much as the patient will know when he has finished reading it.

The Psychoanalysis of the Total Personality: The Application of Freud's Theory of the Ego to the Neuroses. By Franz Alexander, M.D. Authorized English translation by Bernard Glueck, M.D., and Bertram D. Lewin, M.D. With a prefatory note by A. A. Brill, M.D. Boards. Price, $3.50. Pp. 176. Washington, D. C.: Nervous and Mental Disease Publishing Company, 1930.

This volume begins with a foreword by Dr. Brill which traces the evolution of the freudian conception from its first announcement to the present time. Dr. Brill points out that the present volume deals with the development of the ego, its rôle in the neuroses and psychoses, and the basic instinct of the neuroses and perversions. The translators, in their preface, emphasize the practical character of this work and attempt to make clear the peculiar nomenclature with which the freudians surround their discussions. Finally, the author, in his introduction, reveals the fact that he is concerned primarily with the way in which the modern freudian psychology concerns itself with the total personality rather than with the instinct alone. The book consists of nine lectures which distinguish the various conceptions of the ego and the superego, leading to the conclusion that a neurosis represents a conflict between the ego and the instinctive needs. The narcisistic neurosis appears to be a struggle between the ego and the superego. This volume is obviously of more interest to the freudian, and to those who are concerned immediately with the freudian, than to the general reader. For the latter, it will be very slow going; moreover, comprehension will be difficult, and, in some instances, belief will be even more difficult. The freudian conception represents one of the greatest contributions of the twentieth century, but the day is still far distant for its application to general medical practice.

Sertse i Grippoznoe Vospalenie Zubov i Mindalin. Dr. B. A. Egorov. [Heart and Influenza, Paradentitis and Tonsillitis. By Dr. B. A. Egorov.] Paper. Pp. 108, with illustrations. Moscow, 1930.

The author observed cases in which signs and changes of septic endocarditis remained stationary for long periods. Moreover, the intensity of functional changes did not correspond to that of organic changes. Palpitations, cardiac pains, suffocation and dyspnea were considerable, while the cardiac murmurs or occasional dilatation of the heart were insignificant. The third particular feature of the cases consisted in the presence of mental disturbances. Hypochondriasis, melancholia and depression were the signs of a mental reaction. There was a persisting fever. The patient's history pointed always to a sore throat or to influenza as the origin of the "endocarditis." The tonsils proved to be responsible for the fever; removal or cauterization of the tonsils was followed by lowering of the temperature. *Further examination revealed that the cardiac phenomena simulating endocarditis were associated with irritation of a certain section of the sympathetic nervous system.* The connection between a chronic infection of the tonsils and an irritation of the sympathetic cervical and thoracic ganglions is explained as follows: Inflammation of ganglions and of plexuses, mechanical compression of a sympathetic plexus by enlarged cervical glands, also functional hyperemia or ischemia of sympathetic ganglions are factors of irritation of the sympathetic nervous system. Viscerovisceral and axonal reflexes may accompany the vasomotor changes. Variations of blood pressure in vessels of the sympathetic nervous system may assume a certain rôle. Infection of the tonsils or of the periodontal tissues is a frequent cause. Other septic foci, as chronic sinusitis or chronic infection of Highmore's antrum are able to induce an analogous cardiac syndrome. In one

BOOK NOTICES

instance, the latter was caused by chronic tuberculosis of the ear and of the temporal bone. Other forms of an infectious vegetative syndrome may be observed, but the cardiotonsillar form is the most usual. The septic focus in the tonsils was frequently associated with that in the periodontal tissues. In rare cases, septic foci were found in the paranasal sinuses and in the adnexa. Egorov stresses that an acute influenza may result in chronic inflammatory processes, as "grippal sore throat," "glippal periodontitis" or "chronic influenza."

Anatomy. By George W. Corner, M.D., Professor of Anatomy in the University of Rochester. Clio Medica, a series of primers in the history of medicine. Cloth. Price, $1.50. Pp. 82, with 8 illustrations. New York: Paul B. Hoeber, Inc., 1930.

Medicine in the British Isles. By Sir D'Arcy Power, K.B.E., F.R.C.S., Honorary Librarian at the Royal College of Surgeons of England. Clio Medica, a series of primers in the history of medicine. Cloth. Price, $1.50. Pp. 84. New York: Paul B. Hoeber, Inc., 1930.

These two contributions will be greeted with pleasure by all those who love medical history for itself alone or who want their medical history in an easily readable, compact form. The books are essentially monographs of some twenty thousand words. That they do not deal entirely with subjects that are obsolete is apparent by the book by Power, which provides not only a history of the development of medicine in the British Isles but also a picture of the practice of medicine in Great Britain today. Moreover, this, as well as the other book, is supplemented by a bibliography that means much to those who care to look into the matter further.

Reminiscences of George Martin Kober, M.D., LL.D., Emeritus Dean and Professor of Hygiene of the School of Medicine and Member of the Board of Regents, Georgetown University, Washington, D. C. (In Two Volumes.) Volume I. Cloth. Price, $5, per set. Pp. 403, with illustrations. Washington, D. C.: Kober Foundation of Georgetown University, 1930.

Dr. George Martin Kober celebrated his seventieth birthday in 1920. He now presents the first volume of his autobiography, which covers his early life and reminiscenses of Germany, his arrival in the United States, and his relationship to the United States Army through the campaign of General Howard, about 1878. The book is full of interesting personal material; however, the detail is so overwhelming as to make the work forbidding to all except those who have had personal relations or acquaintanceship with its author. Volume I covers a period when the United States and medicine in the United States were undergoing growing pains. No doubt the subsequent volumes will carry the author through the adolescence and maturity of the advancement of medical education and bacterial investigation, in which he has played a considerable part.

The Physiology of the Vestibular Apparatus. By Mario Camis, Director of the Institute of Physiology of the Royal University of Parma. Translated and annotated by R. S. Creed, B.M., B.Ch., M.A. Cloth. Price, $7.50. Pp. 310, with 65 illustrations. Oxford: Clarendon Press, 1920.

This book is the result of much research. After a history of the early work on the physiology of the labyrinth, the anatomic details of the vestibular apparatus and its nervous connections are described in detail. The next chapter deals with operative methods for the study of the labyrinth of animals together with the effect of partial and complete destruction of the labyrinth. Following the experimental stimulation of the labyrinth, the author considers the labyrinth as an organ of the sense of space and then as an organ of reflex function. The relations of the labyrinth to the eye and ocular nystagmus, as well as the analysis of the labyrinthine reflexes are given quite fully. While most of the work deals with animal experimentation, the last chapter is devoted to the examination of the labyrinthine reflexes in man, the adequate stimulus for the sensory organs of the labyrinth and the nervous connections of the vestibular apparatus. This is a scholarly monograph and deserves close study for it contains innumerable important matters, some of which are not as yet entirely clear from either the physiologic or the clinical point of view. The illustrations are good and the translators have rendered the original Italian into excellent English. This work will serve as an excellent reference book for otologists, physiologists and others who are interested in the structure and function of the static apparatus.

The Pathology of Diabetes Mellitus. By Shields Warren, M.D., Pathologist of the New England Deaconess Hospital, Boston. With a foreword by Elliott P. Joslin, M.D. Cloth. Price, $3.75 net. Pp. 212, with 85 illustrations. Philadelphia: Lea & Febiger, 1930.

In this book, which is based on the study of 300 cases, Warren again brings into focus the various phases of the pathology of diabetes. A consideration of the insular hypothesis is followed by the description of the histology of the normal pancreas. The lesions of the pancreas seen in diabetes are then described and compared with lesions observed in the pancreas of nondiabetic individuals. A conclusion at this point is important. "It is striking that practically any lesion found in the pancreas of diabetic individuals, either involving the island tissue, the acinar tissue or both, can be duplicated in the pancreas of nondiabetics." Only the greater frequency of such lesions in diabetic patients justifies their consideration as presumptive evidence of diabetes, and, without information of the previous clinical course or without studies of the glycogen distribution in other organs, the diagnosis of diabetes cannot be made. The complications of diabetes receive attention, especially those associated with or resulting from arteriosclerosis. The importance of arteriosclerosis is evident from the frequency of deaths resulting from it, 72 of the 300 cases. The rôle of infection is equally important, this being the cause of death in 126 cases; syphilis played a minor part. Only two of the deaths were due to syphilis and not a pancreas in the series showed changes attributable to this cause. Tuberculosis accounted for only thirteen deaths. Diabetes in children, hemochromatosis, insulin resistance and hyperinsulinism are discussed, as well as the association with diabetes of other endocrine disorders. This leads to a consideration of theories as to etiology. In the series of 300 diabetic necropsies, the pancreas was available for detailed histologic study in 259. Of these, 69 were normal so far as could be determined and no lesions of other organs were sufficient to explain the existence of diabetes. This again raises the puzzling question of the nature of the pathologic functioning in these relatively frequent instances of diabetes without apparent cause. The book is well written and beautifully illustrated. It is authoritative and should be made available in medical libraries for every student of this disease.

Generations of Adam. By A. L. Wolbarst, M.D. Cloth. Price, $3.50. Pp. 355. New York: Newland Press, 1930.

Dr. Wolbarst is by specialty a urologist. The evolution of medical practice has largely removed the control of the mental aspects of sex life from the urologist to the psychiatrist and the psychoanalyst, although the most advanced urologists are keeping themselves abreast of the changing points of view. There are, of course, in addition, the persons who emphasize the glandular and constitutional aspects of sexual disturbances. This volume by Dr. Wolbarst is addressed to a lay rather than a medical audience, and it bears the endorsement of both physiologists and psychoanalysts. It answers, for those who are likely to propound such questions, the usual inquiries concerning the development of sex, puberty and the problems of masturbation and the sex urge in maturity. The years of practice of the author have caused him to take what might be called an exceedingly modern view of the entire situation. The Victorians will find little in his book to please them. His literary style is easily comprehended, and his directness is refreshing.

A Text-Book of Histology. By Harvey Ernest Jordan, A.M., Ph.D., Professor of Histology and Embryology, University of Virginia. Fifth edition. Cloth. Price, $7. Pp. 857, with 598 illustrations. New York: D. Appleton & Company, 1930.

The fact that this book appears now in the fifth edition in fifteen years attests its popularity with medical students, for whom it was written. Features that have made it popular with them are the clearness of the text and the abundance of the illustrations. There are 594 figures with 4 plates. More than half were made especially for this work and many are based on photographs. The chapters on histologic technic and on directions for laboratory work have made it especially useful in the class room. In this edition the section on the function of the hypophysis has been rewritten and there has been added a new view of bone growth based on the work of Policard and Leriche ascribing a new rôle to osteoblasts, osteoclasts and bone cells. Progress in other fields has been noted mainly by footnotes to the text.

Dietetics for High Schools: A Textbook in Nutrition and Food Economics. By Florence Willard, Chairman of the Department of Home Economics, Washington Irving High School, New York City, N. Y., and Lucy H. Gillett, Superintendent of the Nutrition Bureau, N. Y. A. I. C. P., New York City, N. Y. Second edition. Leatherette. Price, $1.40. Pp. 290, with 28 charts. New York: Macmillan Company, 1930.

This textbook on dietetics is intended as a help to teachers to present the principles of nutrition in a simple yet scientific manner in the last year of junior high school or any year in senior high school. The subject matter is arranged for one year of five recitation periods per week. Problems, questions and references accompany the chapters. The purpose is to awaken the interest of the youthful student in the more prominent facts of the newer knowledge of nutrition, to make him conscious of habits of food health, to provide a simple understanding of the chemistry of foods, and to teach him how to select the food he needs. The subject matter is presented with a view to practical application. Chapters are devoted to the energy value of food, energy requirements of individuals, composition of foods, mineral elements and vitamins. The latter half of the book considers practical food selection in general and for the members of a family of six children of scattered ages, the parents and the grandmother. Planning of meals and purchasing of food to meet body needs and restrictions of the pocketbook are discussed. Forty-one useful tables are given.

Die Therapie der Wiener Spezialärzte. Bearbeitet von den Fachärzten Wiens. Herausgegeben von Dr. Otfried O. Fellner, Frauenarzt in Wien. Third edition. Cloth. Price, 20 marks. Pp. 666. Berlin: Urban & Schwarzenberg, 1930.

A book on therapy, that is the product of more than a hundred medical and surgical specialists of the celebrated Viennese clinic and arranged alphabetically for ready reference, deserves recognition by practitioners who read German. It is so replete with useful, generally orthodox, information, that it is perhaps invidious to point out minor defects, such as excessive fondness for proprietary medicines, on the part of some of the contributors.

Miscellany

REPORT ON MINERS' PHTHISIS IN SOUTH AFRICA

The Miners' Phthisis Medical Bureau of the Union of South Africa in the year ended July 31, 1929, made 45,801 examinations and case investigations. The diagnostic procedure now in use for several years and noted in previous reports has become a standard of the bureau for the diagnosis of silicosis. The continued use of the method has served to confirm it as a standard rather than to produce any modification. Silicosis progresses more rapidly among the African natives who work in the mines than among the European laborers. It is well known that tuberculosis commonly exists in conjunction with silicosis. Obvious tuberculosis was found in 31.4 per cent of 121 cases in which silicosis was found, post mortem, during the year. Evidence of silicosis was found after death in the lungs of fifteen persons whom the bureau had examined within six months of death without finding clinical evidence of silicosis or tuberculosis. The amount of silicosis found by the pathologist in these fifteen cases after death was "very slight" or "slight," except in two cases in which it was classified as "moderate." The bureau examined 22,447 specimens of sputum, of which 2,620 were from Europeans and 19,827 from natives; 15.11 per cent of the former and 16.89 per cent of the latter were positive for tubercle bacilli. Comparatively few specimens of urine were examined. The conclusion drawn was that there is no evidence of a larger number of cases of disordered kidney function among silicotic persons than among those who do not have silicosis. The total number of working miners examined was 15,492, all of whom had previously had an initial or a periodic examination. Among these, 424 were found to have simple silicosis, giving a rate of 2,737 per hundred thousand; 154 of these cases, however, were old cases; that is, miners who had previously been certified as having silicosis. There were, therefore, 270 new cases which originated during the year. The rate at which new cases of silicosis developed for all working miners was 1,761 per hundred thousand, as compared with a rate of 1,941 for the previous year. With one exception, the rate was the lowest on record for the last ten years and was less than half the rate for the year 1925-1926.

During the year, 22 cases of simple silicosis developed among 8,360 "New Rand miners"; that is, those who have been working at scheduled mines only since Aug. 1, 1916. The rate of incidence of new cases among them was, therefore, 263 per hundred thousand. The average duration of underground work of these 22 new cases was nine years and nine months. Among 5,672 "Old Rand miners" (those who commenced work prior to Aug. 1, 1916) there were 197 new cases of silicosis, a rate for them of 3,473 per hundred thousand. The average duration of work in the scheduled mine performed by these 197 miners who became silicotic during the year was twelve years and eleven months.

There has been since the period 1920-1923 a fall in production rates for silicosis of 36 per cent. The reduction was not gradual during the whole period, for there was a marked rise from 1923 to 1926. It is likely that not much, if any, further decrease in the number of cases arising is likely to take place for years to come. The cause for the reduction was given in previous reports by the bureau and was not discussed in detail in the last report. The average duration of underground service of those who contracted silicosis has increased in about ten years from 114 to 151 months. It is necessary to repeat that this reduction in the length of service applies only to those miners who actually contracted silicosis and not to the whole body of working miners. The figures of twelve or thirteen years cannot, therefore, be regarded as an approximate measure of the average effective working life of a miner.

A nontuberculous nodular fibrosis of the lung, due to silica dust, is a distinct pathologic process and is the chief feature of the majority of cases of simple silicosis. This process may advance considerably without being complicated by infection. There exists, however, in most cases of simple silicosis, from the time that it becomes detectable, a latent low grade tuberculous infection, which may be associated with some of the silicotic lesions. These infected lesions may originate from tuberculous foci, dating back to early life, or they may be due to a reinfection occurring during the development of the silicotic lesions. Gye and Kettle have shown that finely divided silica has a specific effect in the selection of the site of tuberculous infection. It is characteristic that a chronic tuberculous infection developing in a silicotic lung is apt to be of low virulence and accompanied by excessive fibroid reaction, resulting in large areas of a massive infective consolidation in which the siliotic nodules are cemented together by organized inflammatory products. To this condition the general term "infective silicosis" or "tuberculosilicosis" has been applied. Uncomplicated silicosis may undergo prolonged and apparently indefinite arrest at any stage: this is also true, to a less extent, of "infective silicosis." While the condition may remain practically stationary for long periods, infection gets the upper hand in the end, and, when that occurs, the greater the amount of original damage to the lung, by silicosis, the more rapid will be the final breakdown.

The great diminution in the amount of dust in mine air has been the chief factor in lessening the incidence of silicosis. That fact, however, is believed to be the chief cause also of a change in the type of the disease to a relatively more infective type and, therefore, to a more progressive type. The effect of great quantities of dust was to produce an excessive fibrosis and this tended in many cases to retard the progress of tuberculosis. There is still the same need for the fullest control of early tuberculosis, that existed formerly when silicosis was more prevalent, because the tendency of the disease toward termination by a tuberculous infection has in no way diminished. Among 15,492 miners undergoing periodic examinations during the year, 44 had simple tuberculosis, a rate of 284 per hundred thousand. This was considerably higher than for the previous year. The report demonstrates plainly that the liability to death bears a direct relation to the relative prominence of the tuberculous factor in each class of case. An early conjunction of active tuberculosis with silicosis produces a condition that is more rapidly fatal than an active simple tuberculosis alone. The report is signed by Dr. Louis H. Irvine, chairman of the Miners' Phthisis Medical Bureau. The personnel of the bureau comprising physicians, medical examiners, radiologists, pathologists, photographers and clerks, did not change during the year.

Medicolegal

Loss of Remaining Eye in Industrial Accident

(Lehman v. Schmahl, State Treasurer, (Minn.), 229 N. W. 553)

Section 4276, G. S. of Minnesota, 1923, provides, in part, as follows:

> If an employe receive an injury, which of itself, would only cause permanent partial disability, but which combined with a previous disability does in fact cause permanent total disability, the employer shall only be liable for the permanent partial disability caused by the subsequent injury.
>
> Provided, however, that in addition to compensation for such permanent partial disability and after the cessation of the payments for the prescribed period of weeks, the employe shall be paid by the state the remainder of the compensation that would be due for permanent total disability, out of a special fund known as the Special Compensation Fund. . . .

Lehman lost the sight of one eye through the formation of a cataract. Subsequently an injury sustained in the course of his employment destroyed the other eye. His employer and the insurance carrier compensated him for permanent partial disability. The industrial commission awarded him the remainder of the compensation payable for permanent total disability, to be paid out of the special compensation fund, established by payments which every employer or his insurance carrier is required to make for every injury causing the death of an employee who leaves no dependents entitled to compensation. The state treasurer, the custodian of the special fund, thereupon appealed to the Supreme Court of Minnesota, contending that the previous partial disability of Lehman resulted from natural causes in no way connected with an industrial accident. The legislature, it was urged, intended to impose on industry liability for disability resulting from industrial accidents but did not intend to impose on industry liability for disabilities resulting from natural causes.

The legislature recognized, the court said, that a partially disabled workman would be handicapped in obtaining employment if the employer were to be held liable for total disability in case a subsequent disability combined with the prior disability should result in total disability. It would be inequitable, too, to require the last employer to bear the entire burden in such cases. The legislature recognized, on the other hand, that where a partially disabled workman suffers an injury which, of itself, would cause only partial disability but which, added to the prior disability, causes total disability, he loses entirely the power to earn which he previously possessed and which he would still possess but for the subsequent injury. To provide for such cases the special compensation fund was created.

Where a workman having but one eye, said the supreme court, loses that, the compensation provided for the loss of one eye, based on the theory that he still retains the use of the other, is far from adequate. The section of the statute quoted was intended to provide for such cases. The incapacity resulting to a workman from the loss of his remaining eye is the same whether he lost the other in an industrial accident or in some other manner. The statute grants the additional compensation where an injury causing partial disability, combined with a *previous disability*, causes total disability. The statute uses the words *previous disability* without in any way limiting the meaning to be given to them. There is nothing to indicate an intention to give the additional compensation only in those cases in which the *previous disability* resulted from an industrial accident. If the legislature had intended the additional relief to be given in such cases only, it would have expressed that intention in the statute.

In view of the liberal construction given to such statutes for the purpose of securing for a disabled workman the benefits intended, the court affirmed the award of the industrial commission.

Death Following Vaccination a Compensable Injury

(Neudeck v. Ford Motor Co. (Mich.), 229 N. W. 438)

The Ford Motor Company ordered the vaccination of its employees, at the request of the Detroit board of health. The claimant's husband, an employee of the company, was so vaccinated and subsequently died. The claimant was awarded compensation by the department of labor and industry and the employer brought certiorari to the Supreme Court of Michigan. It was agreed that the company ordered the employee to be vaccinated, that he was vaccinated by a company physician, and that as a result of the vaccination the employee incurred a streptococcus poisoning, the focus of the infection being the vaccinated arm, from which he died. The company contended that the vaccination was not an accident, and, further, that if the infection was an accident there was no proof that the germs entered the wound at the time of vaccination or when the employee was at work.

In a note to 39 A. L. R. 872, it is stated:

> An external infection which has been distinctly traced to a definite point of contact, such as a scratch or abrasion, and to a definite time, being of an unusual nature and generally happening suddenly or unexpectedly, is generally held to constitute an accident, or an injury by accident, within the meaning of the act.

This rule, said the supreme court, is sustained by the decisions in *Cline* v. *Studebaker Corporation*, 189 Mich. 514, 155 N. W. 519, L. R. A. 1916 C, 1139, and *Blaess* v. *Dolph*, 195 Mich. 137, 161 N. W. 885. In the Cline case an infection developed in the eye of an employee from an attempt of a fellow workman to remove a piece of steel from it. In the Blaess case, an undertaker's assistant became infected through a slight cut on his finger while working on the body of one who had died from infection. In both of these cases the infection was held to be an accident.

The company relied on the case of *Krout* v. *J. L. Hudson Co.*, 200 Mich. 287, 166 N. W. 848, L. R. A. 1918 F, 860, in which an employee was vaccinated by a physician employed by the city board of health and later contracted infection. It was held that the infection was not a compensable accident because there was no evidence that the germs lodged in the employee's arm in the course of employment and no connection was shown between the employment and the infection following vaccination. The present case is readily distinguished from the Krout case, the court said. There the vaccination was by a public agency, independent of the employer and the employment. Here the vaccination was performed by the company's physician and submitted to by the employee under the direct order of the company. Neither the employee nor the company was under the compulsion of public authorities. The vaccination occurred in the course and out of the employment.

The vaccination wound itself was not an accident because it was not an "unforeseen event." Vaccination is usually harmless, but when infection results therefrom the infection is an accident. Of course, no one could testify that he saw a germ enter the wound. The most that could be done would be to state the condition which would render the infection probable or possible. No testimony was introduced to indicate how or when the infection occurred, or to show its cause. It was agreed, however, that the infection was an effect of the vaccination, and this agreement ties the accident of infection to the act of vaccination as occurring in the course of employment.

The award of compensation was accordingly affirmed.

Society Proceedings

COMING MEETINGS

American Society for the Study of Disorders of Speech, Chicago, December 30-January 1. Dr. Sara M. Stinchfield, Mount Holyoke College, South Hadley, Mass., Secretary.

American Society of Tropical Medicine, Cleveland, December 27-30. Dr. Edwin Peterson, U. S. Naval Hospital, Washington, D. C., Secretary.

American Student Health Association, New York City, December 29-30. Dr. D. F. Smiley, Cornell University, Ithaca, N. Y., Secretary.

Society of American Bacteriologists, Boston, December 29-31. Dr. James M. Sherman, Cornell University, Ithaca, N. Y., Secretary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to The Journal in continental United States and Canada for a period of three days. Issues of periodicals are kept on file for a period of five years only. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending, but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Resuscitation of Stopped Heart by Intracardiac Therapy.—Hyman asserts that the success of the intracardiac injection procedure for the resuscitation of the stopped heart is apparently due more to the effect of the puncture wound made in the wall of the heart than to the chemical substance injected. The puncture wound made by the injecting needle becomes a focus of increased irritability from which a stimulus for myocardial contraction may be developed. The first contractions of the heart after injection are always extrasystoles. The initial extrasystolic arrhythmia may give way quickly to a normal sinus rhythm, with prompt recovery on the part of the patient. However, when the period of anoxemia has been so prolonged or so intense that there is considerable disturbance in the electrodynamic factors controlling myocardial contraction, the initial extrasystolic arrhythmia may persist and may be quickly followed by a rapid sequence of ectopic beats. Such a condition leads to pathologic fatigue of the ventricles, which may be followed by ventricular fibrillation. Ventricular fibrillation is an extremely hazardous disturbance of the heart and is usually accompanied by immediate collapse of the circulation and death of the patient. This phenomenon explains the secondary collapse of the circulation often seen following what has apparently been a successful resuscitation of an asystolic heart. It is suggested, therefore, that the intracardiac puncture be made into the right auricle instead of into the ventricles as is now practiced.

Is Climate Responsible Factor in Etiology of Diabetes Mellitus?—Mills feels that one can scarcely avoid the conclusion that climate is, in part at least, responsible for the incidence of diabetes in all races. The regions possessing the most changeable and stimulating climate are the ones with the highest incidence of diabetes. In some of these, it is true, life is intense and complex, and the sugar consumption high, indeed; but in certain others, equally stimulating, almost the same frequency of diabetes is seen without the high sugar consumption to which it is attributed. One is inclined to attribute the increase in diabetes and consumption of sugar to the same cause, namely, overstimulation by a highly changeable climate, leading to a desire for the sugars as readily available producers of energy, but also leading to an increase in diabetes whether this desire for sweets is satisfied or not. The increase is probably much more marked when the prosperity of the people permits them to indulge this desire without stint. Prosperity may also act by lessening the physical effort required, thus making the intake of sugar still more excessive so far as physiologic needs are concerned.

Sugar Consumption in Diabetes Mellitus.—Mills states definitely that consumption of sugar as such is not related in a causal way to the death rate from diabetes.

Improved Indirect Method for Enumeration of Blood Platelets.—The method devised by Olef for the enumeration of platelets adheres to the leading principles that must be taken into consideration in counting platelets: (1) avoidance of contact between the undiluted blood and glassware or metal, (2) mixing of the freshly drawn blood as quickly as possible with the preserving fluid and (3) avoidance of all unnecessary manipulations of the blood. It dispenses with the use of the graduated pipet and counting chamber. It eliminates the errors resulting from the inclusion in the platelet count of degeneration products of erythrocytes ("Arnold bodies") and of finely particulated foreign matter. The results obtained are higher than ever previously obtained by similar methods.

Tropical Sprue.—In sixteen of thirty-six cases reported by Baumgartner and Jewett, the blood picture was similar to that in pernicious anemia; in all but four the condition could be conclusively shown not to be pernicious anemia (Addison), because free hydrochloric acid was found in the stomach, a low blood calcium with or without tetanic reactions was present, or a definitely large dilated colon occurred, which they believe is a characteristic of sprue and is not found in pernicious anemia. Several cases showed a severe secondary type of anemia. Improvement in the general physical condition with a definite return of the appetite almost always occurs with a restriction of carbohydrates and fats in the diet. Liver is valuable as treatment in the severely anemic cases frequently found.

Arteriovenous Difference in Blood Sugar Content.—Glassberg believes that it is not justified, on the basis of present knowledge, to attach a diagnostic significance to the arteriovenous difference in blood sugar content. It remains to be determined whether diabetic patients can be regrouped into two therapeutic or prognostic groups depending on whether the arteriovenous difference in blood sugar content lies within or below the range determined as normal.

Oxygen and Carbon Dioxide in Blood from Internal Jugular and Other Veins.—Lennox measured the oxygen and the carbon dioxide content of the blood from an artery and from various veins in a large series of cases. The gaseous content of blood from the femoral vein was found to be the same as that of blood from a cubital vein. In sharp contrast, blood from the internal jugular vein was more reduced and blood from the external jugular less reduced than from a cubital vein. These statements are true for average values. Measurements for individual patients varied widely. In a series of fifty-one patients, the average corrected respiratory quotient for blood from a cubital vein was 0.84 and from the internal jugular vein, 0.9. More sugar disappeared from the blood in its passage through the brain than in its passage through the arm. The former of these observations suggests that, in the metabolism of the human brain, carbohydrates are unusually important.

T Wave Changes in Electrocardiogram in Coronary Occlusion.—Experimental work cited by Hurxthal shows that increased amplitude of the T wave follows ligation or injury to the muscles supplied by a coronary artery; cooling causes depression of the T wave. Two cases are reported in which records were obtained before and after attacks. One case showed an upright T wave in all leads one hour after the onset of the attack, later followed by depression, whereas the record six days before the attack showed an inverted T wave in lead I. The second case showed a distinct but not diagnostic change one hour and fifteen minutes after onset. It is suggested that electrocardiographic observations be made at more frequent intervals following acute coronary occlusion. Such observations may prove of distinct value in diagnosis.

Carcinoma of Lungs with Metastases to Central Nervous System.—A group of 12 cases selected from 109 in which the condition was diagnosed as primary carcinoma of the lung was studied by Davison and Horwitz from the point of view of metastases of the central nervous system. Three cases showed symptoms of the spinal cord due to compression following invasion and destruction of the vertebra by the metastases. Of 109 cases of primary carcinoma of the lungs investigated, 11 per cent showed involvement of the central nervous system. One of the cases came to necropsy and revealed compression and distortion of the cord without circulatory interference. The onset in most of the cases showing neurologic signs came on suddenly. The most frequent histologic types of primary carcinoma of the lung with or without metastases to the central nervous system were those derived from the bronchi.

Acute Monocytic (Histiocytic) Leukemia.—Two cases are presented by Dameshek in which the diagnosis of acute monocytic leukemia was made. Supravital staining of the blood served to confirm the diagnosis of the type cell, the histiocyte. A review of the literature on the subject is presented. Since the conception of the third form of leukemia is linked intimately with the studies on the reticulo-endothelial system and on the monocyte, these subjects are discussed in some detail. The monocyte appears to be a distinctive cell directly derived from the reticulo-endothelial system. Various disorders of this system have been described: abnormal storage (Gaucher's disease, Niemann-Pick's disease, xanthomatosis); irritations due to infections (monocytosis); tumor growth (endothelioma, reticuloma), and proliferation (leukemia). The proliferative lesions—reticulo-endotheliosis—may be leukemic or aleukemic. Leukemic proliferation results in the clinical entity known as monocytic leukemia. It is thought, therefore, that the third type of leukemia should be added to the two accepted types. Though apparently much rarer than either myelogenous or lymphatic leukemia, clear-cut cases of monocytic leukemia at times appear and should not escape recognition.

Arachnoidism. D. Prey, Denver.—p. 440.

Pathology of Atelectasis and Relation to Pulmonary Infection.—Two fatal cases of bilateral postoperative atelectasis are reported by Johnson. He asserts that atelectasis, especially of the patchy or lobular variety, is a common finding at necropsy, but there have been comparatively few postmortems in cases of postoperative massive collapse. The most satisfactory theory regarding the latter condition is that it is due to a combination of bronchial obstruction with diminished force of respiration. The conditions found in necropsies have not been constant. Bronchial obstruction has been present in some and absent in others. Two necropsies are reported in cases of bilateral postoperative massive collapse in which no obstruction could be found. Atelectatic lung tissue in itself is probably no more susceptible to infection than normal lung, but, if the atelectasis is produced by obstruction with material containing virulent organisms, infection may spread into the obstructed lung with resultant pneumonia.

Atelectasis.—Yegge bases a diagnosis of this condition on the following: In cases that have no history of a chill, and have a sudden onset with dyspnea, cyanosis, rapid pulse and respiration, with fever, a white count between 15,000 and 20,000, and physical signs showing a displaced apex beat toward an area of dulness that at one time shows bronchial breathing and at another decreased breath sounds with a compensatory emphysema in the contralateral lung, and if the sputum is mucopurulent with no blood, one must think of atelectasis. The most conclusive sign in atelectasis is the shifting of the mediastinal structures toward the affected side in unilateral cases.

Etiology of Mexican Typhus Fever.—Zinsser and Castaneda have adduced strong evidence in favor of identifying the virus of Mexican typhus fever with the rickettsiae, or Mooser bodies, observed in the tunica lesions of Mexican typhus guinea-pigs. Were it not for the possible presence of a few remaining cell fragments in the washings, they would consider this evidence crucial proof.

Lice and Bedbugs with Mexican Typhus Fever Virus.—Experiments made by Castaneda and Zinsser have shown that the Mooser bodies, or rickettsiae, derived from guinea-pigs with Mexican typhus fever can survive in bedbugs after intracoelomic injection for ten days, remaining capable of infection. They have also succeeded in similarly infecting bedbugs by allowing them to feed on benzolized rats in whose blood rickettsiae had been shown to be present. Injection of the organs of such bedbugs five days after the last, nine days after the first infectious feeding into guinea-pigs produced typical Mexican typhus fever. Some of the guinea-pigs infected with such bedbug organs and passing through a typical typhus proved to be immune to subsequent inoculation with the European disease. Attempts to infect normal guinea-pigs by allowing infected bedbugs to feed on them or by rubbing the feces into the uninjured skin have so far been unsuccessful.

Experimental Fibrous Osteodystrophy in Hyperparathyroid Dogs.—Experiments made by Jaffe and Bodansky have shown that parathyroid extract-Collip can be injected into puppies in increasing amounts for long periods without fatal results. Thus time is allowed for bone changes to develop. Long continued injection leads to progressive decalcification and resorption of the existing bone, to fibrous replacement of the marrow, and to the production of the other features characteristic of osteitis fibrosa. Deformities eventually appear. It is safe to assume that the bone changes produced by hyperparathyroidization have the same pathogenesis as those observed in clinical cases believed to be instances of hyperparathyroidism —that is, cases with a negative mineral balance and decalcification of the skeleton.

Common Cold.—Human colds have been successfully transmitted by Dochez et al. to apes and human volunteers in 44 per cent of instances tried by means of filtered nasal washings obtained from colds.

Surgery of Infant Abdomen. A. A. Zierold, Minneapolis.—p. 826.

Use of Tannic Acid in Burns of Children.—In 62 per cent of the cases admitted to the Children's Hospital of Michigan during the past three years, the burn was due to some one leaving a pail of hot water unprotected, the filling of a bathtub with hot water, and the child falling into it, or due to a child pulling a kettle of hot water, soup or coffee from a stove, spilling the contents over itself. This suggests that more than 60 per cent of the mortality and morbidity of burns in children is definitely avoidable and due to the negligence or carelessness of some one in leaving a pail of water unprotected or filling a bathtub with very hot water and waiting for it to cool, instead of drawing it at the desired temperature, or permitting a child to play around a stove on which something is cooking. The second important causative factor is playing with matches or around a bonfire. Twenty-five per cent of the cases were of this origin. Davidson describes the treatment employed in these cases and commends highly the use of tannic acid because it lessens toxemia, is analgesic and prevents the loss of body fluid; secondary infection is markedly limited by the absence of a favorable nidus for bacterial growth; scar tissue formation has been less marked than that observed after treatment by other methods; the protective layer of coagulated protein forms a scaffold for the growth of the young epithelial cells over the denuded area.

Effect of Liver and Liver Extract in Pernicious Anemia.—Forty-four cases of pernicious anemia, in which there were symptoms referable to changes in the central nervous system, have been treated by Baker et al. by liver or a combination of liver and liver extract. Of twenty-three cases followed for more than six months, improvement in symptoms and signs has occurred in 55.17 per cent. In twenty-one cases treated for less than six months, improvement was noticed in only 31.25 per cent. In eight cases of outspoken combined degeneration, treated for more than ten months, there was improvement of symptoms and signs in 58.9 per cent. The authors emphasize that it is essential that large quantities of liver, or liver and liver extract, be employed over long periods of time. When the amount of liver is much reduced or is dispensed with, relapses may occur promptly. It seems probable that in pernicious anemia the myelin degeneration may occur in the peripheral nerves and brain, as well as in the spinal cord, and that some of the symptoms and signs that undergo improvement are referable to a peripheral neuritis.

Treatment of Psoriasis Vulgaris with Intravenous Administration of Acriflavine Hydrochloride.—Twenty cases of psoriasis vulgaris treated with intravenous injections of acriflavine hydrochloride are reported by Sweitzer and Allen. All but three cases of the series showed clinical improvement and in four cases the results were striking.

Basal Metabolism of Filipinos.—The metabolism of eighty-eight men and sixteen women was determined by Ocampo et al. by the Benedict-Roth portable metabolism apparatus and found to be —7.8 and —9.3 per cent, respectively, lower than the accepted "Aub-Du Bois Standard." Observations of basal metabolism on two Filipinos while in a temperate climate show no appreciable difference from those made while in the Philippines. The bearing of the present report on the question of racial and climatic factors in metabolism is discussed.

Treatment of Typhoid by Agostinelli's Method.—Forty patients with typhoid were placed under Agostinelli's method of treatment by Guerrero and Ignacio. Fourteen had positive blood culture and the rest had clinical typhoid. Thirty-two recovered; two were unimproved; one improved; five died. The average length of time that these patients remained febrile without treatment was 15.5 days, which means that the disease had already completely developed before they came to the hospital. The average number of days of treatment during the febrile period was 11.5 days, which is probably shorter than the length of ordinary treatment. This agrees with Agostinelli's observation. The average length of the total febrile period was 27.5 days, which is two or three days shorter than the usual duration, since they have observed that about thirty days is the usual febrile period. This does not agree with the observation of Agostinelli that the duration of the disease is shortened to about one half. In one third of the cases there was immediate temporary lowering of the temperature after the first injection, and in some cases the temperature became intermittent in character. Ten of the patients developed complications, and four of them died. Guaiacol and camphor did not seem to have attenuated these complications. Two patients had relapses but recovered under the same treatment. There were no untoward effects of importance. The mortality rate was 12.5 per cent, which was a little lower than that observed in cases under the ordinary treatment. The adjuvant treatments given consisted of horse serum, tincture of digitalis and epinephrine. These were used only when extremely necessary. The authors feel that whatever encouraging results were obtained, such as the slight shortening of the duration of the disease and the lower mortality rate, should not be attributed directly to the effect of the drugs, because it has been their experience that the severity of typhoid may vary from year to year. Agostinelli's technic is as follows: For the first two days, no matter in what period of the disease, hypodermic injection of guaiacol and camphor, 20 cg. each in 1 cc. of olive oil, is given three times a day. From the third day, the dose of each drug is increased to 30 cg. and is given at the same hours. Injections are given as long as there is fever and continued the three days of convalescence following, after which the original 20 cg. dose is resumed. After two days more without fever the morning injection is suspended, and after two days more the evening dose is omitted, until finally the remaining noon injection is discontinued after two more days of convalescence. No other form of treatment is employed and even hydrotherapy is entirely omitted.

Site of Predilection in Cross-Infection from Right to Left Lung.—Cross-infection from the right to the left lung is apparently quite frequent in the presence of destructive infections of the right lung. Cole et al. found that the site of predilection within which cross-infection usually develops is the middle of the left lung, that part of the lung which is projected between the second and fourth ribs in the roentgenogram. Cross-infection is apparently due to the aspiration of infectious exudate and detritus present in the bronchial tree. The site of predilection is apparently in the path of least resistance beyond the termination of the left main bronchus. Posture of the individual may be a factor in this type of aspiration infection, but it seems probable that the sharp intake of breath following a prolonged cough or paroxysm of coughing is a more important factor in driving secretions present in the smaller bronchi into the air vesicles proper. Estimation of prognosis in any given case of pulmonary infection does not depend entirely on the progress or retrogression of the original areas of infection but must take into consideration whether or not there is secondary infection of other parts of the lung.

Cholecystography.—Oral cholecystography has proved a reliable test in the diagnosis of gallbladder disease in Feldman's experience. Eighty-six cases came to operation; of these, a total correct diagnosis was made in 94.2 per cent. The highest percentages of correct diagnoses occurred in cases of stones and in the gallbladders that failed to fill. The diagnostic errors occurred in the cases with poor filling or faint shadows.

Infections of Hand from Human Bite.—Thirteen cases are reported by Mason and Koch. They state that bite infections are frequently prolonged in their course and difficult to clear up because the infection is usually introduced deeply into the tissues through a comparatively small wound, because of the character of the infection, because of the anatomic arrangement of the structures involved, and because of the relatively low resistance of fascia, tendon and bone to a mixed infection such as is caused by the organisms present in the mouth. Such infections when introduced into the tissues of the dorsum of the hand—the most common site of inoculation—tend to spread to definite areas, and this extension depends particularly on the exact site and depth of the primary inoculation and on the ease or difficulty with which the infectious material can escape to the surface. In the treatment of such infections an exact knowledge of the sites to which infection tends to spread is of importance. These are, in order of frequency, the subcutaneous space of the dorsum of the hand, the subfascial space of the dorsum of the proximal phalanx, the subaponeurotic spaces of hand and fingers that lie directly over metacarpal bones and proximal phalanges, the metacarpophalangeal joint, the fascial spaces of the palm, and the flexor tendon sheaths. If these sites are kept in mind, extension of infection can be recognized early and accumulations of pus drained before extensive necrosis of tissue has taken place. Unless such infections are drained early and adequately, bone, joint and tendon involvement are certain to occur and to lead to extensive impairment of function.

Tumors of Parotid Gland.—Benedict and Meigs have made a study of 225 cases with complete records as to pathology and end-results in eighty cases. They conclude: Benign tumors are more common than malignant tumors in the ratio of about four to three. Carcinoma is about twice as common as sarcoma. Cysts, melanotic sarcomas and adenomas are extremely rare. Mixed tumors are essentially benign but recur locally with great frequency. They rarely become malignant. Malignant parotid tumors are difficult to cure. Once the diagnosis is established, they advise early radical operation, including ligation of the external carotid artery and severing of the facial nerve whenever necessary. Patients with mixed tumors live indefinitely. Patients with malignant disease rarely live over two years after operation. Radium and roentgen rays are useful in the treatment of malignant parotid tumors but only as palliative procedures. In the treatment of benign parotid tumors, radiation therapy is of benefit in some cases, but they believe that excision is the treatment of choice. Carcinoma, sarcoma and malignant lymphoma may invade the parotid gland secondarily. Such cases usually end fatally, but one brilliant cure reported here justifies many extensive operations and emphasizes the importance of not giving up in the struggle against malignant disease.

Effects of Electrocautery on Normal Tissues.—In a study made by Gottesman et al. of the effect of the electrocautery incision in the skin, muscle, liver, kidney and spleen in normal adult albino rats, it was found that the electrocautery incision produces extensive necrosis, which acts as a foreign body with a resulting foreign body giant cell reaction. The advantages and the disadvantages of the electrocautery are discussed. The promiscuous use of the electrocautery is discouraged.

Perinephric Abscess.—A clinical study was made by Campbell of eighty-three cases of perinephric abscess. Etiologically the disease is of extrarenal or intrarenal origin and in the majority of cases bacterial metastasis is the mechanism. While the predominant symptoms are fever, loin or costovertebral angle pain, leukocytosis, and reflex urinary frequency, disease other than perirenal abscess may be suggested both subjectively and objectively. With this confusion of symptoms and often meager or indefinite clinical signs, the diagnosis is difficult. In a third of this series the diagnosis was made only at necropsy. Stereoscopic roentgenography is of especial value when it shows obliteration of the psoas muscle margin on the side of the abscess or lateral spinal curvature away from the abscess. Moreover, when complicating subphrenic abscess is present, elevation and fixation of the diaphragmatic dome with costophrenic sinus obliteration is diagnostic. Technical urologic examination may be of no aid and, as they have twice seen, may actually confuse the diagnosis. The treatment is surgical drainage, although rarely a patient recovers without operation. Complications are of frequent incidence and involve the pulmonary and genito-urinary systems in particular. Of fifty-four patients operated on for perineal abscess, eleven died, an operative mortality of 20.4 per cent. It is noteworthy that most of these fatalities were directly due to complications and the surgical treatment rather than to the primary abscess.

Primary Carcinoma of Fallopian Tubes.—Holland asserts that carcinoma of the fallopian tube is not as rare as was formerly believed. Inflammatory changes in the fallopian tubes do not deserve the etiologic significance relative to carcinoma attributed to them by many writers. The proper diagnosis of carcinoma of the fallopian tube can be arrived at only by macroscopic and microscopic examination. From sections examined it would seem that papillary alveolar and alveolar types are advanced stages of primary papillary malignancy. Nine cases are reported

Surgery of Diabetes.—The circular amputation of Kocher is recommended by Maes for diabetic gangrene of the lower extremities, and the gridiron incision is recommended for the treatment of carbuncles of the neck.

Method of Reconstruction of Axilla for Contracture.—In the method employed by Garlock for reconstruction of the axilla, done in stages and consisting essentially of the transplantation of skin flaps from a distance with maintenance of their blood supply through tubed flaps which are in turn utilized in the reconstructive procedure, vertical suture lines are avoided.

Resection of Renal Pelvis for Hydronephrosis.—In eleven cases of hydronephrosis, resection of the renal pelvis was performed by Walters. In eight cases (nine resections) the results of operation were excellent. In four of these cases hydronephrosis was bilateral, and the renal pelvis was large and infected. Bilateral resection was done in one case, with an interval of three months between operations, with excellent results. It has been almost two years since these operations were performed, and the patient has been completely relieved of all symptoms of renal retention or obstruction. This is probably the first successful case in which resection of bilateral infected hydronephrotic kidneys has been reported. In three additional cases of bilateral hydronephrosis, successful resection of one hydronephrotic renal pelvis has been performed. Three months will elapse before the other renal pelvis is resected. Cases of hydronephrosis in which successful results followed division of anomalous blood vessels or connective tissue sheaths are not included in this series of pelvic resections. Three cases in which resection of the renal pelvis was performed required secondary nephrectomy due to (1) persistent urinary fistula from occlusion of the ureter by postoperative infection around the ureter, and (2) pyelonephritis with cortical abscesses in two cases in which urine was being transmitted successfully from the resected renal pelvis to the bladder through the ureter. Complete recovery followed nephrectomy. When postoperative stasis occurred in the renal pelvis, it was successfully relieved by the introduction of an indwelling ureteral catheter through the cystoscope, where it was retained as long as the retention persisted. In spite of leakage of urine from the anastomosis with perirenal accumulation, results may be satisfactory provided drainage is sufficient.

Transplantation of Head and Shaft of Fibula to Humerus.—Behrend reports a case discussed here dealing with nonunion of a comminuted fracture of the humerus followed by a low grade type of osteomyelitis due no doubt to the various kinds of material used to hold the fracture in place to assist in the union of the two fragments of the humerus. Numerous trials at reduction were made but without success. Many types of splints in addition to plaster casts were used but failed to keep the fractured ends together. It required six open operations before success was attained. Behrend used Parham bands on two occasions, a Sherman plate, a tibial bone graft, and finally the fibular graft. The patient now has a good arm, the flail arm being replaced by a firm one—which is useful although the range of movement is somewhat reduced as compared with the normal. There is also some radial nerve palsy, which is mending slowly.

Injuries to Semilunar Cartilages of Knee Joint.—Henderson says that if repeated locking has occurred, or if the complaint cannot be relieved in primary cases by manipulation, and the condition is causing inconvenience to the patient, other things being equal, there is no reason for withholding the benefits of operation, and the offending meniscus should be removed. General anesthesia is favored, but the operation can be carried out under local anesthesia by the infiltration method about the knee or a combined caudal and spinal injection. The latter has the advantage over the infiltration method as it permits the use of the tourniquet. Of the 256 patients 238 have been traced; 183 are relieved of all trouble; 34 are improved, and 21 are not improved; thus, 91 per cent were cured or markedly improved. There have been no fatalities in the series, and no infection more serious than a low-grade skin infection in a few of the cases. There were forty-two cases in which, at the time of operation, the lesion present was not sufficient to account for the patient's symptoms, but because of the definite subjective symptoms the meniscus was removed. Thirty-five patients were traced. Thirteen (37 per cent) were cured, eight (23 per cent) were improved, and fourteen (40 per cent) were not improved.

Hypertrophic Ostearthritis of Spine.—Eighty unselected patients over 40 years of age were studied by Cottrell to determine the incidence of ostearthritis of the spine and the frequency of an associated radicular syndrome. Of these, 44 per cent showed evidence of hypertrophic ostearthritis. The average age of the patients was 55.6 years. The dorsolumbar region was the most often involved. Throat cultures from the forty-four showing ostearthritis did not yield *Streptococcus cardioarthritidis* in any instance. Focal infection was present in 56 per cent of all cases and in 68 per cent of cases showing ostearthritis. Twenty-five, 31 per cent, showed by neurologic examination evidence of pressure on the spinal nerve roots. In seventeen, 21 per cent, no symptoms were found attributable to the arthritis. Eight, 10 per cent, had the radicular syndrome in which the complaint was entirely due to this condition. Four of the eight had ostearthritis, whereas four had none visible to the roentgen ray. Of the eight patients with the radicular syndrome, five had been operated on without relief. In five the radicular syndrome simulated visceral disease.

Malignant Growths of Stomach.—Among 2,612 necropsies reviewed by Brindley and Wolfe there were 57 instances of malignant growths involving the stomach, a percentage of 2.14. A study was made of the period of time intervening between the onset of symptoms and death. Of those cases in which this could be determined, 71.9 per cent of the patients lived less than a year after the symptoms began; 18.8 per cent lived between one and two years, and 9.3 per cent lived over two years. Approximately half of the patients whose previous history could be determined did not mention having any gastric trouble. In studying the mode of onset of the gastric disturbances they found that 78.6 per cent showed gradual onset of symptoms, while in 21.4 per cent the onset was sudden. The earliest symptoms given at the onset of the terminal illness were vomiting and pain, equally common; next in order of frequency were epigastric discomfort, weakness, and loss of weight. Pain was present sometime during the illness in 67.6 per cent of the cases. Food caused increase of pain in half the cases. Vomiting was present at some time during the course of the disease in approximately two thirds of the cases. Of those cases in which vomiting had occurred, 47.4 per cent gave a history of the vomitus at some time having been bloody or coffee ground in character. Constipation was present in 77 per cent; diarrhea in 11.5 per cent, while a normal condition of the bowels was present in 11.5 per cent of the cases. Physical examination revealed emaciation in 91.4 per cent of the cases; 5.77 per cent well nourished, and 2.9 per cent obese. Abdominal palpation revealed an epigastric mass in 45 per cent and tenderness in 37 per cent of cases. Summation of laboratory observations showed free hydrochloric acid 10 or less in 84.2 per cent. Total acidity was below 10 in 40 per cent of cases. Lactic acid was present in three fourths of the cases. Gross blood was present in a little more than a third, and occult blood in 72.3 per cent. Boas-Oppler bacilli were found in 40 per cent of cases; 71.4 per cent of the cases were diagnosed as gastric malignancy; 26.3 per cent were diagnosed as some other condition, while in one case no diagnosis was made. At necropsy, 90 per cent of tumors were found to be primary in the stomach. Of the other cases, two first appeared in the esophagus, one started as a melanosarcoma of the eye, and one as a sarcoma of the thigh. In three fourths of the cases the tumor site was in the pyloric region of the stomach and near the lesser curvature. Secondary deposits from primary growths in the stomach occurred in the following order of frequency: lymph nodes, 75 per cent; liver, 55 per cent; peritoneum, 22 per cent; lungs, pancreas and kidneys, each 17 per cent; omentum, 14 per cent; intestine, 10 per cent; diaphragm and pleura, each 8 per cent; bone, 6 per cent; esophagus, retroperitoneal glands and suprarenals, each 5 per cent; duodenum, 1 per cent. Microscopic examinations of the malignant tissues show an adenocarcinomatous arrangement of the cells to be slightly more frequent than a cell mass of simplex arrangement. In two cases mucinous degeneration of the tumor cells was present, these cases being typical colloid carcinomas.

Value of Complement Fixation Test in Tuberculosis.—Terrell has found that carefully conducted complement fixation tests should yield from 60 to 70 per cent positive reactions in cases of tuberculosis, depending on the stage of the disease. The test acts as a stimulus to more careful observation, and as an aid only when considered in conjunction with a complete history and physical investigation.

Treatment of Diabetes Tested by Stress and Strain of Life.—The kind of foodstuffs, rather than the number of grams and calories of food principles, has been the diet prescription used by Fain et al. for a number of years. The results have been so encouraging that they believe them unequaled. Foundation of the diet is green vegetables two or three times a day, fruits (preferably fresh fruits) twice a day, fresh meat (rather animal protein, whether fish, fowl, eggs or cheese), cream and butter. Cereals and potatoes are added if the tolerance of the patient for blood sugar producing foods will permit. Each serving of fruit is limited to an amount that contains approximately 12 Gm. of carbohydrate; vegetables, six or nine tablespoonfuls of 3 per cent three times a day and six or nine tablespoonfuls of 6 per cent twice a day. One or more of these vegetables should be raw. Two or three ounces of meat or its equivalent in fish, fowl, eggs or cheese three times a day; the fat, besides that in the meat daily, is given in 20 per cent cream and in butter given as such or in soup and on vegetables. Oil dressing is given on salad. To this is added for the diabetic patient, three times a day, one, two or three palatable muffins. For a muffin or muffins, a doughnut, cracker, piece of cake or some pleasing substitute may be given. Each muffin contains approximately 2 Gm. each of carbohydrate, protein and fat. If this is not enough food to keep the patient on his feet and at his usual occupation, potatoes and cereals are added to meet the energy requirements of the individual. If the patient can handle the maintenance amount of food for him and keep the urine sugar free and the blood sugar within fairly normal limits, insulin is not given. If the maintenance amount of food is not so taken care of, insulin is given once, twice or three times a day. With this outline of diet as a basis, it is only exceptional cases that require as much as 60 units of insulin a day. When dealing with an individual whose maintenance is below the ordinary diet as given here, the authors have found that it is most satisfactory to decrease the fat first and then, if necessary, the protein before any lowering of the fruits and vegetables is attempted.

Anesthesia for Operations on Gravid Uterus.—Featherstone is of the opinion that gas-oxygen is the best agent for general anesthesia for obstetrician and gynecologist. Spinal analgesia has an important place in the technic of cesarean section. Hysterectomy of the gravid uterus in the later stages of pregnancy is a severe procedure. Most frequently the operation is called for in the presence of concealed accidental hemorrhage, or for severe sepsis in the pelvic organs. It is one of the most anxious operations of surgery. The patient is toxic, suffering from shock, and bloodless. The more powerful anesthetic agents, chloroform and ether, disturb the patient too much; their use is followed by serious postoperative reaction, and pneumonia or failure of the heart or kidneys may follow. Spinal analgesia may produce a dangerous fall in blood pressure in a patient who is already nearly pulseless. Gas-oxygen is a most valuable aid. Eight cesarean hysterectomies were performed under gas and oxygen for concealed accidental hemorrhage; each patient was nearly in a dying condition when the operation was commenced. One patient died half an hour after the operation was completed; one died on the sixteenth day, but the remaining six recovered.

Outbreak of Food Poisoning in Staffordshire.—Clayton and Milne describe some characteristics of a hog cholera bacillus which was responsible for an outbreak of food poisoning. The main features were the presence of two subtypes, and the high serologic specificity of the cultures when the organisms were at first isolated. There were eight cases in this series with three fatalities.

Tuberculosis and Public Health.—MacGregor says that in Glasgow practically no impression is being made on the death rate from phthisis affecting young adults of either sex between 15 and 25 years of age. This type appears to have remained unaffected in both incidence and severity. On the other hand, a remarkable fall in phthisis at later ages has taken place in both sexes, most markedly among women. It would appear as if tuberculosis were rapidly declining as a chronic disorder of the middle-aged but remaining unaffected as an acute disorder of young adults. Till within recent years Scotland has had a relatively high incidence of nonpulmonary tuberculosis. For one thing, it is said that dairy herds in this country have ten times as much tuberculosis as those in America. Whatever is the reason, however, since the first decade of the century the death rates from these forms of the disease have declined at a more accelerated pace compared with the rate of fall for the pulmonary form. As regards mortality, tuberculous meningitis is one third, abdominal tuberculosis one fifth, and other forms two fifths of the rates then prevailing. Along with this, there has been noticeable a decided diminution in the severity assumed by the various forms of tuberculosis at the younger ages of life, applying particularly to glandular and abdominal disease, but also to bone and joint disorders, which are showing less tendency to rapid abscess formation, while amyloid disease is now seldom encountered. The greatest fall has taken place in abdominal tuberculosis—a fact of considerable significance, as this disorder is mostly bovine in origin. Although something has been accomplished under the Tuberculosis Order in eliminating grosser disease from among dairy herds, such a wholesale improvement can scarcely be credited to this cause. It appears much more likely that the greatly increased practice of pasteurization of ordinary city milk, to which from 80 to 90 per cent of the supply has been subjected for some years, has interposed a degree of protection against transmission of this form of tuberculous infection.

Personal Experiences in Midwifery.—After five years' experience with mercurochrome in glycerin, Ford considers that this is a reliable, harmless and absolutely efficacious antiseptic as far as the endometrium is concerned, and, possibly, for all mucous membranes. The suggestion is made that 1/100 *grain (0.6 mg.) of scopolamine in 2 cc. of sterile 50 per cent* magnesium sulphate solution is a safe and fairly effective analgesic for labor.

Staining of Calcium.—Alizarin in Cameron's opinion is a nearly specific stain for calcium. It reacts readily in vitro and in vivo with recently deposited calcium phosphate or carbonate, normal or pathologic, but often fails to stain older deposits. This limits its practical utility.

Pathology in Fatal Case of Psittacosis.—In the case described by Wilson the lung changes are those of a pneumonia of unusual type, which does not correspond to any ordinary pneumonia, whether occurring as a primary disease or as a secondary complication. The general picture is that of a septicemia accompanied by distinctive changes in the lungs. These are, in the order of their occurrence, congestion with abundant serous exudation, which ultimately becomes fibrinous; degeneration and desquamation of the epithelium lining the air vesicles and bronchi, and thrombosis of capillaries or actual necrosis of the walls of the air vesicles in areas where the damage is more severe, with hemorrhage in places. A relative absence of polymorphonuclear leukocytes is a striking feature and is consistent with the leukopenia observed clinically and with the microscopic appearances of the bone marrow. The histologic picture suggests that the changes in the lungs may be the result of intense toxic damage rather than an inflammatory reaction, but it is of course possible that this is an extreme example in which the marrow was almost completely inhibited and that less severe cases might show a different response. The occurrence of a terminal bronchopneumonia, however, shows that a leukocytic reaction to pyogenic infection was still possible, and as the changes in this area are so strikingly different from those in the main lesions it would appear reasonable to suggest that the lesion in psittacosis is characteristically not accompanied by reaction on the part of the polymorphonuclear leukocytes, except where secondary pyogenic infection has occurred. It would appear also that such changes as have been described are an adequate explanation of the peculiar "silence" of the lung that has been observed in typical cases. Bronchopneumonia may undoubtedly occur, but this is probably the result of secondary pyogenic infection and not an essential feature of the disease.

Persistent Eosinophilia.—A case of persistent eosinophilia with splenomegaly and massive infiltration of the iliopsoas muscles is described by Drennan and Biggart. A suggestion is made that the syndrome "persistent eosinophilia and splenomegaly" may possibly be a functional disease—an expression of an excessive response on the part of the eosinophil to some as yet unidentified irritant.

Tuberculosis of Stomach.—In the case reported by Cullinan, diagnosis was not possible during life. No primary focus of infection was discovered, nor were there other tuberculous ulcers in the intestinal tract. There was recent pleurisy with adhesions over both lungs. The surfaces of the lungs were studded with miliary tubercles, and the cut surfaces showed generalized miliary tuberculosis. No primary or old tuberculous focus was found in the lungs, and the bronchial glands were unaffected. On the lesser curvature of the stomach, near the cardiac end, was a shaggy soggy mass, like neither a simple nor a malignant ulcer, but looking as though it might be tuberculous. Along the lesser curvature was a chain of enlarged glands. In the cecum there was a transverse ulcer, but all the other abdominal organs appeared natural. It was evident that the miliary disease of the lungs was more recent than the lesion in the stomach, and an effort was made to find a primary focus but without avail.

Liver Extract Effective in Pernicious Anemia.—It is suggested by Wright and Arthur that liver extract acts in pernicious anemia by promoting the due degeneration of the megaloblastic phase of erythropoiesis.

Sacral Chordoma with Widespread Metastases.—The primary tumor in Willis's case was one of the largest, if not actually the largest, so far described. It weighed approximately 200 ounces (5.6 Kg.). Prolific remote metastases, *probably due to tumor invasion of the iliac veins,* were present in the lungs, heart, liver, spleen, kidneys, thyroid and skin. There were numerous exostoses of many bones. The possibility that these and the chordal tumor may both be expressions of a constitutional tendency to skeletal anomalies is discussed.

Pathogenesis of Experimental Poliomyelitis.—The course of poliomyelitis following intrasciatic inoculation is described by Hurst. The order of appearance of virus and lesions in the various regions of the central nervous system accords with the view already expressed that the axons are the main transmitting structures in the disease. The cerebrospinal *fluid plays a subsidiary part in the dissemination of the* virus, which may on occasion be detected in the fluid.

Value of Alkalis in Treatment of Chronic Nephritis.—Osman summarizes the results of this method of treatment in certain types of chronic nephritis during the past seven years. He says that alkalis may be used with advantage in many types of nephritis under certain circumstances, for either their prophylactic or their therapeutic value. They should never be used except with some specific object in view. The frequent practice of giving "small" doses in the hope that they "might do some good" is bad medicine and should be condemned. He reports only forty cases, which represent only a small proportion of those treated by this method and are, in fact, the first forty so treated in which the history of the illness was long enough (seldom less than six months, and in one case as long as fourteen years) to make spontaneous remission or improvement during treatment unlikely. With few exceptions, the symptoms were sufficiently severe to necessitate confinement to bed for at least three months before treatment was commenced. Further, most of them had previously been treated by the usual methods—such as sweating, purgation, salt depletion, urea, high protein diets, thyroid extract, purine diuretics, or decapsulation—without conspicuous success. The results of treatment have been judged chiefly by the effect produced on the immediate symptoms and the subsequent benefit to the patient. The mortality in the forty cases of this series, in a period of five years, was seventeen, or 37 per cent, while in a group of the first forty cases of as nearly the same types as could be found in the records over a similar period, treated by other methods, it was nineteen, or 43 per cent. The similarity in the mortality rates of the two groups is interpreted as signifying that the cases selected for this review constitute a fair sample of severe types of chronic nephritis. The chief value of alkalis in the treatment of nephritis consists in their action in promoting diuresis and thus ridding the tissues of excess water or edema. Therefore, they have been found of most use in cases of chronic nephritis accompanied by considerable amounts of edema and oliguria—i. e., in chronic parenchymatous and chronic "mixed" nephritis, in which dropsy not due to an associated heart failure is the most prominent symptom. As some decrease in the plasma bicarbonate appears to be the rule in all types of chronic nephritis, it seems reasonable to suppose that alkalis, by increasing the blood bicarbonate, might be of some value. It has also been found that if alkalis, in the form of equal parts of potassium citrate and sodium bicarbonate, are given by mouth, in amounts sufficient to raise the plasma bicarbonate to, and to maintain it at, a normal level under all circumstances of diet and exercise, it is often possible to induce a diuresis sufficient in degree and duration to rid the body entirely of edema. If, after the edema has subsided, the dose is readjusted to that which will, under the new conditions, maintain the plasma bicarbonate at a normal level, the edema often does not return. Of the forty cases, six were labeled acute parenchymatous nephritis. The remaining cases were of the chronic parenchymatous or chronic "mixed" varieties, and all the patients were suffering from marked edema, which had been persistently present since the onset of the illness. Cases in which there was a history of spontaneous remission of the edema have not been included. In thirty-six of the forty cases, a sufficient diuresis was produced and maintained to cause complete disappearance of the edema. In only four cases did the treatment fail to influence the edema at all. Of the thirty-six cases in which the edema disappeared under treatment, it recurred in four, while active treatment was still being pursued. In these cases it was not found possible to maintain a sufficient diuresis for a long enough period to control the edema. In thirty-two out of the forty cases, therefore —i. e., in 80 per cent—it was possible to obtain complete and lasting control over this symptom. The average period occupied by the treatment was from six to eight weeks.

Postvaricella Purulent Meningitis with Cortical Reaction.—Laignel-Lavastine et al. report a fatal case of purulent meningitis with cortical reaction, subsequent to varicella. The patient, a youth, aged 18 years, convalescent from a seemingly benign attack of varicella, presented a febrile meningeal syndrome with convulsions. The topography of the meningeal lesions, predominant in the anterior and lower parts of the left hemisphere, explains the special symptoms observed: frontal cephalalgia, more marked on the left, left ptosis with anesthesia in the region of the frontal nerve, and epileptiform attacks beginning in the right side of the face. The patient died within three days. There was no local source of infection that could explain the etiology of the meningitis. The hypothesis of a tuberculous origin was eliminated by examination of the cerebrospinal fluid for tubercle bacilli and by inoculation of guinea-pigs. Bacteriologic examination and cultures of the vesicles of the varicella did not reveal any microbial elements that could explain a theory of meningitis by distant secondary infection. It seems logical, therefore, to consider the meningitis in this case as the direct result of the varicella, probably caused by a neurotropic virus, independent of the particular conditions of virulence. The authors consider this case another example of the nervous localizations that are observed in rare instances during the course of or subsequent to varicella.

Vaccinotherapy in Acute Articular Rheumatism.—Loeper and Degos describe ten typical cases of acute articular rheumatism in which they used vaccine treatment. All the patients had resisted treatment by sodium salicylate. The method used was as follows: Preliminary intradermoreaction tests were made with streptococcus, staphylococcus, pneumococcus and gonococcus vaccines. In seven cases a definite positive reaction to one or more of the vaccines was observed; namely, one staphylococcic, one streptococcic, one gonococcic, one mixed streptococcic and gonococcic, and three streptococcic-staphylococcic. Six of the seven patients were cured by injections of the vaccines to which they had shown a positive intradermoreaction. The seventh, who had shown a rather mild reaction to streptococcus vaccine, was cured by a combination of sodium salicylate with the vaccine. The authors feel that these results justify making a preliminary intradermoreaction test in cases that do not yield to sodium salicylate so that vaccinotherapy may be employed when a positive reaction is secured.

18: 273-336 (Sept.) 1930

History of Home for Needy Children of Paris. A. B. Marfan.—p. 273.
*Treatment of Habitual Vomiting and Congenital Stenosis of Pylorus. A. B. Marfan.—p. 289.

Treatment of Habitual Vomiting and Congenital Stenosis of Pylorus.—In Marfan's opinion, most cases of continuous vomiting in nurslings are either simple examples of a disease of habitual vomiting or are due to a congenital hypertrophic stenosis of the pylorus. Since the second diagnosis can be made only after clinical observation during several days and after roentgen examination, the best procedure is first to apply the treatment for ordinary habitual vomiting. This consists of careful attention to diet and general hygienic conditions and also of specific antisyphilitic and antiemetic treatment. It is necessary, above all things, to nourish the infant sufficiently to avoid dangerous conditions of inanition. The mother's milk is the best food in most cases, and only in rare instances does a child show absolute intolerance of it. Ass's milk is the next choice. If it is not available, however, separated cow's milk with a little sugar may be used, as well as various equivalent preparations of condensed or powdered milk. Bouillon and gruel of cereals and vegetables may be given to children more than 3 months of age. The meals should in general be small and frequent, the quantity of nourishment and the intervals between repasts being increased as the treatment progresses. The nourishment should usually be given with a spoon in order to determine the exact amount ingested and to avoid suction, and the liquid should be cold or even iced. In some cases, if the nourishment meets with complete intolerance when so administered, it is necessary to give it drop by drop on the infant's tongue. Extreme care should be taken to insure the most comfortable conditions for the patient—quiet, fresh air, soft light, often a complete change of environment. Since congenital syphilis is often the source of habitual vomiting in nurslings, antisyphilitic treatment, usually by mercury, should be given, which in many cases brings immediate relief. Antiemetic treatments such as enemas and antidyspeptic medicaments, especially bismuth subnitrate, are also valuable in ordinary cases. In the severe forms of the disease, antispasmodic medicaments should replace antidyspeptics; tincture of belladonna is recommended. If after about ten days the general treatment is of no avail, surgical intervention is usually necessary. If tubage shows a prolonged gastric stasis, and if it shows alimentary residues in the stomach more than four hours after the last meal, the existence of a pyloric stenosis is almost certain. This may be determined by roentgen examination, after ingestion of a bouillon containing a bismuth or barium salt, which clearly reveals impermeability of the pylorus. The diagnosis once established, the operation should be performed as soon as possible. In most cases a longitudinal extramucosal pylorotomy will be the most effective and safest method. However, when this seems insufficient, because of some circumstance such as the extreme hardness of the tumor, a gastro-enterostomy may be used with excellent results.

Presse Médicale, Paris

38: 1361-1376 (Oct. 8) 1930

*Insulin in Treatment of Cardiac Insufficiency. M. Loeper, A. Lemaire and R. Degos.—p. 1361.

*Therapeutic Action of Sugar in Cardiac Insufficiency. N. Kisthinios and D. M. Gomez.—p. 1363.

*Use of Physostigmine Salicylate for Regularization of General Anesthesia. L. Garrelon, G. Pascalis and L. Thuillant.—p. 1365.

Insulin in Treatment of Cardiac Insufficiency.—Loeper et al. advocate the use of insulin combined with dextrose in the treatment of cardiac disturbances. They find that when administered alone it relieves cardiac insufficiency, that it considerably reenforces and prolongs the action of other cardiants, and that it also aids in the specific treatment of syphilis. The action of insulin thus used is twofold: it acts directly on the nutrition of the myocardia and also produces equilibrium of the two functions of glycolysis and glycogenesis. In their experiments the authors used insulin both alone and in connection with other medicaments. Subcutaneous injections of from 5 to 10 units of insulin were given each morning. Fifteen or twenty minutes later the patients were given 100 Gm. of dextrose syrup (about 50 Gm. of dextrose). The immediate results of the injection were a sensation of fatigue, followed shortly by a marked sensation of increased physical resistance. The effects on the arterial tension and cardiac rhythm were noticeable after about the third injection.

Therapeutic Action of Sugar in Cardiac Insufficiency.—Kisthinios and Gomez describe several cases of cardiac insufficiency that had resisted treatment by ouabain and digitalis and in which immediate amelioration was produced and the patients were eventually cured by the administration of dextrose and insulin. Daily doses of 80 Gm. of saturated dextrose syrup were given, and twenty minutes later 4 units of insulin was injected. A lactovegetarian, dechlorinated diet was maintained. Although dextrose, like digitalis, sometimes acts as a diuretic, its pharmacodynamic action is due to its direct effect on the muscles of the heart, since it is efficacious in many cases in which the quantity of urine is already abnormally high. Moreover, the effect of dextrose on the cardiac muscles has long been established through numerous experiments. The authors suggest that a combined treatment with dextrose and ouabain might be valuable, analogous to the combination of ouabain and digitalis that has been used in certain cases in which digitalis alone had been inefficacious.

Physostigmine Salicylate for Regularization of General Anesthesia.—Garrelon et al. have found physostigmine salicylate a valuable aid in the anesthetization of patients who do not yield readily to ordinary anesthetics. Resistance to anesthesia may be predetermined by the fact that in such patients ocular compression either does not influence the pulse rate or causes an acceleration. In anesthetizing one series of patients the authors gave a preliminary subcutaneous injection of pantopium hydrochloricum. Half an hour later they administered ether or chloroform. If the patient did not yield to the anesthetic they then injected 0.5 mg. of physostigmine salicylate. Within one or two minutes the respiration was regularized and agitation ceased, although the patients continued to talk and laugh freely. The abdominal wall was completely relaxed, however, and the surgeon was able to perform any operation with security. As soon as the mask was removed the patients regained consciousness with exceptional rapidity and had no recollection of pain. In a second series of patients a preliminary injection, usually of morphine, was given, together with an injection of physostigmine salicylate. The patients were taken to the operating room in a condition that often permitted immediate intervention, without true psychic sleep. The authors suggest the development of this method for minor operations. The same action is produced by physostigmine salicylate in local anesthesia.

Revue Neurologique, Paris

Disturbances in Speech in Course of Pseudobulbar Conditions. G. Lévy. —p. 289.

*Semeiologic Value of Distal Unipolar Electrical Stimulation in Dystonias of Extrapyramidal Origin. V. Néri.—p. 309.

*Primary Juvenile Paralysis Agitans. L. van Bogaert.—p. 315.

Blepharonystagmus. L. Benedek and E. de Thurzo.—p. 327.

Distal Unipolar Electrical Stimulation in Dystonias of Extrapyramidal Origin.—Cathodal stimulation of the lower extremity of the triceps, with the forearm at right angles to the arm, normally provokes extension of the forearm. Néri shows, however, that in dystonias of extrapyramidal origin distal excitation produces no contraction whatever at first; when the intensity of the current is slightly increased, it provokes a slow and progressive flexion of the fingers and hand, and at times a flexion of the forearm toward the arm. A similar reaction may be produced in the muscles of the leg. The diffusion of current thus observed is clearly distinguishable from diffusions due to perturbation of the peripheral motor neuron, because the contraction of the hand is slow and vibrant, whereas in diffusions of peripheral origin the contractions are brusque. It was observed that the application of heat, for instance a cloth dipped in water of from 40 to 50 C., is capable of transforming the flexion into a normal pronation. Cold applications, on the other hand, can cause a normal person to react with flexion of the hand. Since a temperature incapable of modifying the electrical excitability of the nerves or the muscular contractions is able to disturb the direct excitability of the muscles, and since consequently the action of heat and cold is manifest not on the myofibril but on the sarcoplasm, the author suggests that perhaps extrapyramidal dystonias have their origin in perturbations of the sarcoplasm linked with perturbation of the corpus striatum.

Primary Juvenile Paralysis Agitans.—Van Bogaert describes a form of juvenile paralysis agitans that may develop early (in the case reported at the age of 7), and that evolves slowly. There is a marked predominance of phenomena of the various excitomotors, an almost complete absence of hypertonia, and the precocious appearance of definite pseudobulbar symptoms. The tremor, in its graphic and clinical characteristics, is a true parkinsonian tremor. The disease is clinically distinct from Wilson's disease. It is difficult, however, if not impossible, to differentiate it from pseudosclerosis. In spite of clinical indications, the patients do not present hepatic lesions resembling those of hepatolenticular degeneration. From the anatomic standpoint there is a marked lesion of the pallidal system and a lesser lesion of the putaminocaudate system. The locus niger and Luys's body are affected by the degeneration.

The disease behaves as an abiotrophy essentially pallidal but susceptible to diffusion through other systems physiologically associated.

Conjunctivitis Caused by Ultraviolet Irradiation Cured by Administration of Calcium. R. Bárány.—p. 922.

Gonin's Operation for Treatment of Detachment of Retina.—Knapp points out that in most cases of detachment of the retina there also exists a fissure in the retina. Undoubtedly there is a causal relation between the fissure and the detachment; however, not every tear in the retina necessarily leads to detachment. Gonin was the first to utilize, in therapy, the relation between the fissure and the detachment. He has proved that if the fissure is closed by means of cauterization the detachment of the retina can be cured in many instances. It is essential that the operation be performed as early as possible. Of primary importance and at the same time the most difficult part of the operation is the correct location of the fissure. Advice is given as to how it may be most easily located. The operation itself is comparatively simple and is done following subconjunctival injection of procaine hydrochloride to which epinephrine has been added. A sclerotomy is performed and through the scleral opening cauterization is done. The cauterization into the vitreous body has the object to close the opening in the retina by means of reactive inflammation, and also to fix the retina to the wall of the eyeball. In the second part of the article the author describes three cases in which he employed the treatment successfully.

Resection of Lumbar Sympathicus. M. Ronzini.—p. 742.

Recklinghausen's Disease, or Osteitis Fibrosa.—Ferrero and Cucco bring out that osteitis fibrosa may occur in a localized or in a generalized form. To the former belong those cases with solitary bone cysts surrounded by fibrous tissue. The generalized form of osteitis fibrosa involves, however, various segments of the skeleton. The circumscribed form is found usually in young persons, while the generalized form attacks more commonly adults. The long bones are those most frequently attacked by the disease; then, in descending order of frequency, come the vertebrae, the bones of the base of the cranium, the upper and the lower maxillary, and, finally, the flat bones of the thorax and the pelvis; more rarely the metatarsals, the turbinals and the vomer. Of the long bones, the femur is involved in 38 per cent of the cases, the tibia in 22 per cent, and the humerus in 16 per cent. The etiology of Recklinghausen's disease is obscure and various authors advance different opinions. Recklinghausen thought that the disease was of an inflammatory nature, but he did not think that the inflammatory process had its seat in the bone marrow. The fibrosis of the bone marrow, which is the first change that appears, instead of being a process of recovery from the inflammatory disorder, must be regarded as similar in nature to that of malignant tumors, since it attacks and replaces more and more extensive areas of bone. In the localized type, a recovery is often effected after the breakdown of the cystic walls, so that some authors have suggested breaking up the cysts artificially as a mode of treatment. In other cases, puncture is employed or the cyst itself is opened. This treatment will not result favorably if the process of fibrous transformation in the bone marrow is very extensive. In that case, resection of the diseased area is advisable and is followed by the substitution of a piece of bone taken preferably from the patient himself. In the generalized form of the disease, many methods have been tried but without much success. The authors refer to a case of Recklinghausen's disease in a woman, aged 46, which was followed up for several years and carefully studied from the anatomopathologic and the clinical points of view. Various therapeutic measures were tried and a brilliant result was finally obtained by homoplastic transplantation of an ovary. Roentgen examination six months after the foregoing intervention revealed a better calcification, absorption of the cystic cavities, and excellent consolidation of the fractured area.

Gastroduodenal Ulcer in the Child.—De Toni summarizes various types of gastroduodenal ulcers in children and points out the relative frequency of so-called secondary ulcers, whereas primary ulcers are rare—the only ulcers comparable, as a clinical entity, to the round simple ulcer such as occurs in adults. The cases of such disease hitherto described, occurring in children under 12 years of age, are about forty in number. The author adds a personal observation concerning a child, aged 10, in whom, in the absence of all premonitory disturbances of the gastro-enteric apparatus, a syndrome appeared suddenly that, the author felt, justified him in the diagnosis of gastric ulcer. Profuse hemorrhages appeared, recurring several times, which led to the death of the patient, the surgeons having considered operative intervention inopportune. Necropsy confirmed the existence of an ulcer on the posterior wall of the stomach, near the greater curvature. Microscopic examination showed that the ulcer was probably of recent origin. Only two weeks had elapsed from the appearance of the first symptoms involving the gastro-intestinal tract, till death. After discussing the symptoms that justify a diagnosis of gastroduodenal ulcer, the author emphasizes that such ulcers in children tend to have a rapid clinical course. Therefore, when facing a sure, or even probable, diagnosis, it is imprudent to hesitate—surgical intervention should be resorted to without losing further time.

*Electrocardiogram in Congenital Heart Diseases in Children. I. Soriani. —p. 647.

Electrocardiogram in Congenital Heart Diseases in Children.—Soriani describes the method and technic used in his electrocardiographic study of nineteen children aged from 4 months to 12 years. In the interpretation of his results, the author excludes two cases (one of primary cardiomegaly in which the electrocardiograms yielded the characteristic so-called looking-glass tracings, and the other of dexiocardia, in which the electrocardiograms showed a preponderant curve of the right ventricular type). Of the remaining seventeen cases in which the existence of congenital heart disease or heart lesion was proved, in ten the electrocardiograms showed right ventricular preponderance, in two a left ventricular preponderance and in five the electrocardiograms were almost normal. The electrocardiographic method has not therefore an absolute value in the diagnosis of congenital heart disease in children. It is, however, a good adjuvant method in association with other modern methods of examination of the heart. The author considers that before the age of 3 months the right ventricular preponderance is normal and should not be taken into consideration in the diagnosis of heart diseases in younger infants.

*Structure and Function of Cells of Tuber Cinereum. U. Poppi.—p. 1382.
Peculiar Syndrome Caused by Lymphosarcoma of Jejunum. F. Benedetti-Valentini.—p. 1383.

Structure and Function of Cells of Tuber Cinereum.—Poppi points out that the principal nuclei of the tuber cinereum contain a large amount of fat (consisting, in part, of lipoids), which causes the displacement of the chromatic substance. These cells contain in addition numerous siderophilous granules of a lipoid nature similar to those common to the cells of the hypophysis and the suprarenals. The author recalls the researches of Abel, Collin and Sato, respectively, who found in the tuber cinereum an active principle equal to that of the posterior lobe of the hypophysis, and raises the question whether these cells have a simple reservoir function or whether they have an endocrine function of their own.

*Intraligamentous Extra-Uterine Pregnancy with Living Fetus Complicating Ovarian Cyst. F. Tallaferro and E. Thwaites Lastra.—p. 245.
*Treatment of Genital Pruritus with Radioactive Mud. J. Iribarne and J. L. Sardi.—p. 259.

Extra-Uterine Pregnancy with Living Fetus Complicating Ovarian Cyst.—Tallaferro and Thwaites Lastra say that, in cases of extra-uterine pregnancy complicating an ovarian cyst, the factor which offers more difficulties for the surgeon and which endangers the patient's life is that related with the treatment of the placenta, especially when the pregnancy has advanced to near term. Removal of the placenta should be the treatment of choice. A good hemostasis should be secured before it is removed. In cases in which a satisfactory hemostasis cannot be obtained, a Mikulicz drain should be inserted. It has the double advantage of controlling hemorrhage and favoring the expulsion of retained placental fragments. If removal of the placenta may endanger the patient's life, the treatment used by American authors (in which the placenta is left, enclosed in the fetal cyst, the latter being closed and marsupialized) seems preferable. The results of this method, however, are not as yet well known. The publication of statistics, containing a larger number of cases than those which have been reported hitherto with this method, is advisable in order that its utility and importance can be evaluated. In the authors' case, the patient, aged 34, had had only one child, one year after her marriage. Since then she had acquired gonorrhea and had been sterile for fifteen years. During the previous seven months the patient had amenorrhea, interrupted at the second, third and fourth months by attacks of lypothymia, slight loss of blood through the genitalia, and pains (similar to those of labor). The severe attack which the patient presented on admission to the hospital was similar to the previous attack, though more intense. When a laparotomy was performed an intraligamentous extra-uterine pregnancy, complicating an intraligamentous ovarian cyst, was found. On the opening of the fetal cyst, a living fetus of normal weight, which lived for some hours, was delivered. It had a cranial deformity, polydactylism and ankylosis of the joints of the legs. The cyst and placenta were removed and a hysterectomy was performed. The patient recovered.

Treatment of Genital Pruritus with Radioactive Mud.—Iribarne and Sardi praise the therapeutic value of radioactive mud in the treatment of pruritus vulvae. It has a weak but constant analgesic action on chronic inflammatory processes and a stimulating action on the local vitality of the tissues. The radioactive substance is used in the form of a poultice in direct contact, through gauze, with the vulva. The poultice is applied when the patient retires and is held in place by means of a T bandage. The next morning the poultice is removed. The treatment is repeated for five consecutive nights. In cases observed by the authors (twelve patients, ages ranging from 28 to 51 years) the pruritus had lasted for from one year to ten years. Ten patients obtained a complete recovery from the treatment (one of this group was a diabetic patient). One of the patients improved and in one of them the treatment failed.

*Identification of Colorless Prodigiosus Bacilli. G. Schad.—p. 99.
*Tarred Streets as Cause of Cancer. K. B. Lehmann.—p. 105.
*Anthrax of Intestine in Man. N. Solowieff.—p. 132.
*Test for Respiratory Capacity. F. H. Lorentz.—p. 378.
*Mortar with Cellophane Guard. H. Dold.—p. 386.

Identification of Colorless Prodigiosus Bacilli.—Schad describes experiments in which he demonstrated that when prodigiosus bacilli lose their power to form pigments they do not lose their agglutination properties. Therefore agglutination tests may be used for the identification of colorless prodigiosus bacilli.

Tarred Streets as Cause of Cancer.—In determinations of the tar content of the air raised from tarred streets by the passage of automobiles over them, Lehmann found that during an eight hour ride approximately 10 meters behind an automobile on a tarred street only 1.5 mg. of tar passed off into the air. He believes that this amount is too small to make tarred streets a factor of any importance in the etiology of cancer either of the skin or of the lungs.

Anthrax of Intestine in Man: Pathologic Changes.—Solowieff reports the observations he made at the postmortem examination of twenty-two persons who had died from intestinal anthrax. It was noted that in cases in which malignant pustules of the skin had appeared first and had persisted for more than four days, lesions resembling carbuncles of the skin were found in the intestine. In seven of the twenty-two cases, lesions of this type were found in the mesentery of the small intestine and of the large intestine. Most of the lesions resembled a cherry in size and color and microscopically they were found to consist of a collection of leukocytes and erythrocytes (most of which showed degenerative changes) and large numbers of anthrax bacilli. In all the cases a condition resembling malignant edema of the skin was found in the intestine. The inflammation was usually of a phlegmonous nature and was always limited to a segment of the intestine from 10 to 12 cm.

long. This part of the intestine was always greatly thickened as a result of edema and a cellular infiltration; the edematous intestine and the peritoneum in its vicinity were dark red from a diffuse infiltration of blood. The cecum and the portion of the small intestine immediately adjacent to it were involved most frequently (twelve cases) and then followed the transverse colon (six cases), the ascending colon (two cases), the descending colon (one case), and the rectum (one case). In three of the cases there were also thickenings in the wall of the small intestine. In the cases of anthrax typhlitis the cecum was thickened and into its lumen projected a tumor resembling the cervix of the uterus. The cecal valve had disappeared in the enlargement and on the mucosa there were superficial ulcers the size of a pea. Some of the follicles were distinctly visible because of a moderate hyperplasia. The lymph nodes of the mesentery were usually enlarged in the region of the inflammation but not elswhere.

Test for Respiratory Capacity.—Lorentz states that from the practical standpoint enough information can be obtained concerning the respiratory capacity from the spirometric index. The size and expansion capacity of the thorax are not reliable as indicators of the respiratory capacity.

Mortar with Cellophane Guard.—For the safe pulverization of bacteria and irritant and poisonous substances, Dold recommends that a cellophane guard be placed over the mortar.

*Electrolyte Composition of Blood in Case of Diabetes Insipidus. M. Gradwohl.—p. 1700.

So-Called Blue Reaction in Icterus.—Van den Bergh et al. direct attention to Brugsch's "blue reaction." Brugsch claims that the blue discoloration of the skin, noted in certain forms of icterus, following the intradermal injection of a small amount of a 1 per cent solution of potassium ferricyanide, is due to the presence in the skin of bivalent iron. Dietrich investigated Brugsch's theory and comes to the conclusion that the blue reaction is not due to the presence of bivalent iron but rather to the oxidation of bilirubin. The authors likewise investigated this problem and their observations corroborate Dietrich's claims rather than Brugsch's. Examination by an experienced microchemist, of a bluish discolored portion of the skin of a patient with icterus, did not reveal the presence of iron.

Clinical Aspects of Duodenal Diverticulitis.—Albrecht reports his observations on fifty patients with duodenal diverticula. The diverticula may be found on all parts of the duodenum; however, they are most frequent on the pars descendens and in the region of the papilla but are rarely found on the pars superior. While in congenital diverticula of the digestive tube usually all parts of the intestinal wall are involved, in acquired pulsion diverticula only the mucosa, submucosa and serosa are generally involved. Duodenal diverticula may be considered as acquired pulsion diverticula due to congenital predisposition. The author also discusses the roentgen diagnosis of duodenal diverticula. It is further pointed out that in many instances diverticula are entirely harmless, but, whenever the diverticulum shows a tendency for retention of foods, bacterial disintegration sets in and inflammations develop. The latter are often followed by hemorrhage, abscess, gangrene and perforation. Perforation in the neighboring tissues involves most frequently the pancreas. In many instances, pancreatitis is noted. The symptoms of the secondary diseases that develop from duodenal diverticulitis frequently predominate to such an extent that the causal diverticulum is overlooked. Disorders that may result from duodenal diverticulitis are duodenitis, gastritis, and, if the diverticulum is in the region of the papilla, frequently infections of the bile and pancreatic ducts. Regarding the therapy of duodenal diverticula, it is stated that those which have no disturbing effects do not require treatment. However, those which have a tendency to retention of foods require treatment. In the beginning internal therapy is usually attempted, but if the disorders recur frequently surgical treatment is advisable.

Electrolyte Composition of Blood in Case of Diabetes Insipidus.—In a case of this disease, a considerable increase in the potassium content of the blood and especially of the serum was noted by Gradwohl. The calcium content, however, showed a relative decrease and the sodium content a marked increase. The water resorption capacity of the normal erythrocytes was considerably increased. Under the influence of a preparation of the posterior lobe of the hypophysis, the potassium values returned to normal. On the other hand, the sodium content was somewhat increased. The normal erythrocytes in the serum of the patient with diabetes insipidus did not show an increased swelling. Tests on the electrolyte composition of the blood of patients without metabolic disturbances proved that the potassium and calcium values were not noticeably influenced by the injection of hormonal substances of the posterior lobe of the hypophysis.

Primary Treatment of Wounds.—More than ten years of experience with the treatment of accidental wounds in a mining section, seeing from ten to fifteen new cases every day, Hansen says, has convinced Magnus's associates of the great value of excision and suture of every type of wound. Drainage is never employed. No especial effort is made to cleanse the area surrounding the wound; a local disinfectant is used; the edges of the wound are trimmed carefully and then sutured with thread, silk or catgut. A dry sterile dressing is applied and completes the operation. Of course, antitetanic serum is used freely.

Experimental Production of Metastases.—Läwen and Müller report on experiments made to produce metastases into joints by various mechanical measures, such as bandaging, the use of tourniquets, the intravenous injection of pathogenic bacteria and their toxins, and deprivation of vitamins in the food. All attempts to achieve the result aimed at were futile.

Effect of Biopsy on Malignant Tumors.—Hanser asserts that in cases of tumors a biopsy is often essential to making a diagnosis of malignancy. He denies that a malignant growth is ever induced by such a procedure. Often it is possible to remove a malignant tumor completely, without later recurrence, by such early diagnosis. Two instances are referred to in which a biopsy was done twice on a carcinoma and the tumor disappeared completely. The incidence of metastases is not increased.

Traumatic Arterial Aneurysm of Palmar Arch.—Volkmann relates two cases in order to call attention to the fact that heretofore such cases have probably escaped being detected. They comprise about 1 per cent of all aneurysms. The symptoms may not be helpful in arriving at a diagnosis. Sixty-seven *cases already recorded in the literature are summarized.*

Local Metastases in Breast Cancer.—Schloffer has been able to trace definitely 149 cases of breast cancer in which he operated at least five years ago. Of this number, 49.5 per cent of the patients succumbed to distant metastases. During the first five years, 2.6 per cent had local metastases; the same percentage had lenticular metastases; 6.1 per cent had axillary metastases and 7 per cent had metastases in the supraclavicular lymph nodes. He feels that some of these metastases could have been prevented by more extensive dissection of local tissues than was done. In several of the supraclavicular lymph node cases, internal metastases were also present. The only modification in the technic of operation, in his opinion, should consist in wider excision of the skin. No fear need be had that too much skin will be excised.

Surgical Treatment of Echinococcus Disease.—Gerulanos has observed 564 cases of echinococcus disease involving all the thoracic and abdominal organs (liver, 386 cases), the breast, thyroid, orbit, muscles, bones and spinal column. He describes the technic employed in various types of echinococcus cyst, stressing the importance of so-called primary suture, and that it is not necessary to drain. The essential point to bear in mind is early operation, as delay from day to day will increase the dangers of this infestation and militate against a favorable outcome.

Treatment of Gastric and Duodenal Ulcers.—Resection, in Reichel's opinion, should be the operation of choice. Gastro-enterostomy, with a large opening on the posterior wall of the stomach, should be reserved for those in whom resection is contraindicated because of the existence of conditions in an individual which point to the exercise of caution in performing any surgical procedure.

Obliteration of Distal Portion of Bowel After Colostomy.—Lewin calls attention to the fact that after a colostomy has been done for a chronic ulcerous stenosing process of the rectum it is never necessary to resect the distal portion of the bowel because it will eventually obliterate itself completely by shrinkage. Equally important, therefore, is it never to close the colostomy opening. He cites in detail, including microscopic examination, the case of a woman who died twenty-four years after the colostomy operation and also cites briefly several similar cases recorded in the literature.

Roentgen Therapy of Prostatic Hypertrophy.—Braeunig and Gruhn advocate this treatment, with vasectomy, in these cases. They describe their technic. Even in cases with complete retention of urine and considerable damage of the kidney and severe degrees of infection of the urinary passages, a cure has been effected. Carcinoma of the prostate and adenoma of the isthmus which causes complete retention of urine are not cases suitable for this treatment. The authors have treated thirty-eight cases and present a brief summary of each.

Preliminary Transplantation of Bone.—Axhausen describes his experiences with the preliminary transplantation of bone into the lower jaw in cases demanding later resection of part of the jawbone. The transplant is buried in the soft parts of the jaw and sometime later—a month or more—the operation is performed on the jaw. At that time it is found that the transplant has become an integral part of the locale; it effectually resists infections and insures a satisfactory result. The method was described by the author in 1928. Now he reports a series of cases in which it was used in lower jaw cases; bone defects, osteomyelitis, lengthening of the lower jaw, tabetic defects with much scar tissue, and even fistulas.

Making Blood Transfusion Safe.—Schöne feels that failure to safeguard the donor has led to disastrous consequences. The position of donor and donee makes it possible for blood to spurt from the donee to the donor, leading to infection with syphilis or with bacteria or toxins contained in the blood of the former. He urges that they should not be permitted to lie in contact or even close to each other. Oehlecker's method is preferred over others.

Amyloidosis of Brain Caused by Roentgen Ray.—Fischer and Holfelder report the case of a man who had received many treatments with the roentgen ray in the course of two years for a cancroid on the temple without effecting a cure. After three years the ulcer was excised and the defect covered with a skin flap. Except for this, he had always been a strong, healthy man. About five years after he had been subjected to the roentgen treatment he had thermic sensory disturbances, became restless, perspired a great deal, had a numb feeling in the left hand and sometimes cramps, also in the left leg. Eventually he had attacks of aphasia lasting five or ten minutes, recurring two or four times a week. A brain metastasis from the original cancroid was suspected. Finally, the brain was exposed in the temporal zone. A piece of it was excised and on examination proved to contain areas of amyloid degeneration. In view of the absence of any recurrence of the cancroid in the skin, the underlying bone, the meninges or the brain, the authors believe that they are justified in concluding that the roentgen ray was responsible for the development of amyloid disease.

Anatomy of Gasserian Ganglion.—On the basis of his anatomic study of this ganglion, van Nouhuys asserts that Frazier's method of subtotal resection of the sensory root is not a reliable radical operation because, if one third of this root is conserved, assurance is not had that it does not contain fibers going to the maxillary or the mandibular roots, which would make a recurrence possible.

Surgical Treatment of Dupuytren's Contracture of the Fingers.—Ritter describes his technic, which consists of making a number of small transverse incisions by means of which tendons are lengthened without being first completely divided and reunited. It is a conservative rather than a radical operation; it is not mutilating and is very effective.

Action of Roentgen Irradiation on Regulation of Blood Sugar.—According to Held, a differentiation must be made between the general action of roentgen irradiation on the regulation of blood sugar and the direct action on the transformation of sugar in the irradiated area itself. In experiments on rabbits and dogs he found that the general action of roentgen rays on the blood sugar regulation, which is manifested by hyperglycemia, is caused by the products of the roentgen reaction. This was demonstrated by the appearance of hyperglycemia in animals following the reinjection of irradiated blood. The causal factors are to be sought in the increased hydrogen ion concentration, the transmineralization and the denaturation products of protein. The direct action of the rays was studied by a comparison of the capillary and venous blood sugar in an irradiated and in a nonirradiated posterior extremity. It was shown that muscle cells also may participate actively in the blood sugar regulation. In the absorption area of the rays there occurred a relative hypoglycemia caused by a direct reaction to the rays.

Blood Pressure Variations Following Roentgen Irradiations, and Their Clinical Significance.—Pausdorf and Nell state that the blood pressure variations that occur immediately after a roentgen irradiation are to be separated etiologically from the variations that occur from twenty-four to forty-eight hours later. Although the former are irregular and variable, the latter follow a definite wave-shaped course that is repeated after from twenty-five to thirty-five days and after from fifty to seventy days. The decrease in the blood pressure is not caused by the action of the roentgen rays on the suprarenals but is the expression of a general reaction caused by marked cellular degeneration and by the hyperirritability of the vasodilator apparatus.

Sarcoma of Uterus: Indications for Roentgen Treatment.—In sarcoma of the uterus, Béclère recommends postoperative roentgen irradiations as a prophylactic measure to prevent recurrences. As a palliative measure roentgen irradiations are indicated in all inoperable cases, in all cases in which operation is contraindicated or is refused by the patient, in all cases of recurrence and in all cases of metastases, regardless of their location.

Lymphogranulomatosis: Roentgen Treatment.—Billich thinks that in the past the doses of roentgen rays used in the treatment of lymphogranulomatosis have been too large. In the treatment of thirty-one persons with this condition he obtained good results with minimal doses of roentgen rays. In cases in which the lymph nodes are soft, only from 20 to 30 per cent of a unit skin dose is used. By the use of such small doses both intense decomposition of protein with its accompanying disturbances and injuries of the skin are avoided. As routine treatment a radiation of medium hardness of from 170 to 180 kv. and 5 milliamperes through a zinc filter 0.5 mm. thick and an aluminum filter 1 mm. thick at a focal distance of 30 cm. is used. As adjuvant treatment, intravenous injections of thoron may be given.

Lymphogranulomatosis: Roentgen Treatment.—Doornkaat-Koolman reports a case of lymphogranulomatosis in a boy, aged 11, who came under observation in 1924 with enlarged lymph nodes in the occipital region, neck, inguinal region and in the region of the hilus of the lung. The treatment consisted of four series of high voltage roentgen irradiations that were given from June, 1924, to May, 1925, and of repeated sojourns in high mountains. Since the beginning of 1926 the patient has been completely cured clinically; his physical development has been excellent and he has been able to lead an active life.

Agranulocytic Angina: Roentgen Treatment.—For the treatment of agranulocytic angina, Burgheim recommends irradiation of the bone marrow in a large number of the long bones with small doses of hard, filtered roentgen rays.

Situs Viscerum Inversus Totalis. W. W. Weinberg.—p. 1230.
Congenital Tuberculosis. M. Zarfl.—p. 1231.
*Eye Diseases During Childhood. K. Safar.—p. 1232.

Embolism of Renal Vessels Caused by Cancer Tissue.—Froewis describes the case of a woman, aged 58, who had cancer of the rectum. Because the growth was inoperable, the surgical treatment was limited to the formation of an artificial anus. The cancer perforated into the vagina and the patient died sixteen days after the operation. The necropsy revealed, besides the squamous cell epithelioma in the rectum, metastases in the lungs, liver, spleen and suprarenals. The kidneys were of normal size but section revealed that the lumen of numerous vessels and of the glomeruli were thrombosed by cancer tissue. Otherwise the kidneys were free from metastases. This case proves that cancer cells may be carried into the glomeruli, and it is probable that these cells lead to the development of renal metastases.

Eye Diseases During Childhood.—Safar discusses the causes and treatment of eye diseases that occur during childhood He mentions suppurative conjunctivitis of the new-born and dacryocystitis. Malformations such as anophthalmos, microphthalmos, colobomas of the iris and of the choroid, and ectopia lentis with tremulous iris, the physician should recognize, although treatment is not possible. However, the recognition of a cataract is significant because an operation should be performed as soon as the general condition of the child permits it. Glaucoma may also occur during childhood, and it is usually accompanied by enlargement of the eyeball. In such cases, early operation can check the further enlargement of the eye and the impairment of the vision. The author further discusses glioma of the retina, acute conjunctivitis, membranous conjunctivitis, paralysis of accommodation, blepharitis in scrofulous children, suppuration of the lacrimal sac, eczematous inflammation of the eye and interstitial keratitis. Of the diseases of the fundus oculi he mentions retinitis pigmentosa, and the ocular disorders in children with amaurotic family idiocy. In children with oxycephaly or with other cranial deformities there sometimes exists choked disk or atrophy of the optic nerve. In cases of rickets, tetany and diabetes, cataract formation is frequent. The author discusses also strabismus and refraction anomalies.

Differential Diagnosis and Treatment of Early Tuberculous Infiltrates.—Roentgenograms of an acute or chronic, indurated pneumonia, bronchopneumonia, postpneumonic sequelae and atelectatic pulmonary areas with peribronchial or endobronchial foci may appear identical with those of a perifocal inflammation. Roentgenograms of circumscribed early tuberculous foci may resemble those of tumors or their metastases. The differential diagnosis is based on the outline of the tumor and on the age of the patient. Tuberculous infiltrates located in a pulmonary lobe must be differentiated from lobar carcinoma. A pulmonary abscess or a circumscribed gangrenous focus of the lung may occasionally be mistaken for a nontuberculous perifocal inflammation. Examination of the sputum and the course of the disease are important in the differential diagnosis. The prognosis of an early infiltrate is favorable when the treatment starts in the beginning of the disease. In most of the cases observed, the diagnosis was not made before a pulmonary cavity developed. Rest treatment, continued for weeks, may suffice in the beginning when there is a tendency to resorption and cicatrization. Any irritative therapy is contraindicated. Artificial pneumothorax is the method of choice in cases in which disintegration of the infiltrate occurs. The treatment was followed by a rapid improvement of the pulse and by a decrease in the fever. Expectoration was frequently reduced one or two months after the beginning of the treatment. Gradual slowing of the accelerated sedimentation of the blood, favorable changes in the leukocyte picture and gain in body weight were recorded in all patients treated with pneumothorax. The latter was usually continued for from one to one and one-half years; in only a few cases was the duration of the treatment considerably reduced. The treatment was continued for at least six months after the general condition became good and the blood reaction and roentgenograms became normal. The treatment proved effective in patients with an advanced pulmonary cavity. Serous exudate was found in 30 per cent of advanced cases in which extensive metastases were present; purulent exudate was not observed. In three instances there was distortion of the mediastinal organs; in one, it was associated with slight circulatory disturbances. An active process developing on the other side could in the beginning be arrested by absolute rest in bed. If not, pneumothorax was induced and that on the other side was discontinued when fever and bacilli had disappeared for months. Otherwise there was a pneumothorax on each side. An easy occupation could often be resumed a few months after the beginning of the pneumothorax. Observation was continued for years after the pneumothorax had been discontinued. Dorendorf induced pneumothorax in ninety-four patients with an early tuberculous infiltrate. Forty-four were reexamined. Twenty-four apparently recovered; they were able to resume their occupation; in the remainder, the improvement was notable.

Study of Experimental Tuberculous Reinfection.—Schnieder's experiments were conducted on rabbits. The reinfection as well as the infection was practiced in the animal's cornea. About 0.002 mg. of B C G vaccine was used for the infection and 0.0000017 mg. (about 800 bacilli) for the reinfection. The interval between the complete healing of the corneal tissue after the first infection and the reinfection was from 280 to 290 days. In three instances, the tissue reactions were similar to those observed on transformation of an early infiltrate in a cavity. In others the reactions resembled those observed on formation of an early infiltrate. In most of the animals, the infection remained latent for seventeen days. Then the infectious process developed gradually. In the first three animals, infiltration of the reinjected tissue appeared the first day; the necrotic infiltrate was eliminated on the sixth day. A holelike defect of the cornea resulted; it was followed by protrusion of the contents of the eye. In two instances there was a secondary infection and destruction of the eye. In the third instance, the corneal defect soon became filled with a new tissue; the form of the cornea was restored within thirty days. At the same time, the controls developed a progressive tuberculosis of the eye. The results tend to explain why tissue reactions sometimes result in an infiltration alone, while sometimes the latter develops into a cavity. Allergy and immunity do not appear simultaneously in the infected area and in the whole organism; namely, first local allergy and then local immunity develop; general allergy and general immunity appear later. Moreover, the local allergy and the local immunity persist longer than the general allergy and the general immunity. At the end of an infection, allergy persists after immunity has disappeared; it persists longer in the local focus than in the whole organism. The allergy may sometimes prove to be sufficient in the defense against tubercle bacilli as it is against other bacilli. Otherwise, there is formation of a sequestrum and an early cavity develops.

*Effect of Intravenous Injection of Insulin on Gastric Secretion. K. Roholm.—p. 472.
Pneumothorax: Pathology and Physiology of Lung. A. F. Lindblom. —p. 493.

Effect of Intravenous Injection of Insulin on Blood Sugar Curve.—Hess Thaysen studied the blood sugar curve of twenty-one persons with diabetes mellitus following the intravenous injection of 12 units of insulin. He noted that in the mildest cases the assimilation line showed the normal steep, almost straight fall, most often from a hyperglycemic value to the lowest blood sugar value, and this was followed (usually at an acute angle) by the ascending or restoration line. In the more severe cases the assimilation line began as a steep fall, sometimes from a high hyperglycemic value, and continued then as a less rapid fall to the lowest point in the blood sugar curve. When the fasting blood sugar was brought down toward the normal limit in such cases, the first fall in the assimilation line was less pronounced and the difference between the assimilation lines of diabetic persons and of normal persons became more pronounced because of the less abrupt fall in the assimilation line of the former. In the most severe cases the first, rapid fall from a hyperglycemic value was replaced by a more slowly falling, slanting line that was followed by a gently sloping arched line that continued to the lowest point of the assimilation line. Frequently in the severe cases and less frequently in the moderately severe and mild cases there were irregularities in the course of the assimilation line in the form of a sudden, steep but brief rise followed by a sudden fall. In mild cases the restoration line did not differ essentially from the one seen in normal persons. It had a distinct primary and secondary rise but it never reached the original blood sugar value within the examination period. In the moderately severe cases, as a rule, the rise in the restoration line was less pronounced and a distinction between the primary and secondary rises was occasionally absent. This was true particularly in the severe cases. The restoration line sometimes showed irregularities in its course, as a sudden rise followed by a sudden fall.

Effect of Intravenous Injection of Insulin on Gastric Secretion.—Roholm studied the gastric secretion of nine normal persons as controls and of sixteen normal persons following the intravenous injection of 12 international units of insulin. It was noted that insulin stimulated the gastric secretion quantitatively and qualitatively. The amount of gastric juice was increased every ten minutes from 10 or 12 cc. to 16 or 18 cc. A smaller increase during the first twenty minutes of the experiment was replaced by a brief fall; this was followed by a greater increase that began about thirty minutes after the injection and reached its maximum from fifty to sixty minutes after the injection. From then on there was a gradual fall until the end of the experiment. Examination of the gastric juice with regard to its acidity revealed that during the first twenty-five minutes following the intravenous administration of insulin there was a slight primary rise that was followed by a fall. After about thirty minutes there was a marked and rapid rise in the acid production until the maximum was reached (about sixty minutes after the injection), corresponding with phenolphthalein values of from 100 to 140. Then the acidity fell slowly and two hours and ten minutes after the injection it had returned to normal. The pepsin content of the gastric juice following the intravenous injection of insulin showed an increase that was concurrent with the increase in its amount and acidity. Individual variations in the pepsin content, however, were far greater than the variations in the acidity, which is consistent with the well known fact that there is not a constant parallelism between the acid and the pepsin secretion of the stomach.

*Treatment of Pernicious Anemia with Dried Stomach. S. A. Holbøll. —p. 825.
*Treatment of Ileus with Hypertonic Solution of Sodium Chloride. E. Schnohr.—p. 831.

Treatment of Pernicious Anemia with Dried Stomach.—Holbøll finds that the results of this treatment correspond to those obtained by treatment with liver. The rise in the hemoglobin percentage and erythrocyte count in two cases described was rapid and marked, while the increase in the number of reticulocytes was not on the same scale as in liver treatment. On termination of the reticulocyte reaction due to the stomach preparation, treatment with liver extract did not cause a new reticulocyte reaction, showing that the active principle in the stomach is identical with the active principle in the liver.

Treatment of Ileus with Hypertonic Solution of Sodium Chloride.—Schnohr says that in high ileus a syndrome consisting of hypochloremia, azotemia and alkalosis has been established experimentally and often clinically. He reports four cases with symptoms of ileus in which the abundant administration of sodium chloride in the form of injections of a hypertonic solution resulted in the restoration of peristalsis in all the patients, two of whom recovered.

THE INDUSTRIAL PHYSICIAN AND THE GENERAL PRACTITIONER [*]

C. O. SAPPINGTON, M.D., DR.P.H.

AND

N. D. MARBAKER, M.D. [†]

CHICAGO

The scientific origin of industrial hygiene is usually dated from the publication of a treatise on diseases of occupation entitled "De Morbis Artificium Diatriba" in the year 1700 by Prof. Bernardo Ramazzini of the University of Padua. Since that time great strides have been made in the study of diseases of occupation and the many ramifications of industrial health work. Mention might well be made of some of the outstanding events showing the importance of the development of industrial medicine.

According to Dr. Harry Mock, the first physical examinations of which there is any record were done by Dr. Frank Fulton of Providence, R. I., in 1906. These examinations were made free of charge for the purpose of discovering tuberculous workmen. In 1909, Dr. Mock began examining employees of Sears, Roebuck & Company, in Chicago, and this practice was speedily followed by other pioneers in the field of industrial medicine. The first official section on industrial hygiene was inaugurated in 1914 by the American Public Health Association.

The year 1915 was particularly significant in the history of industrial medicine. Three events of outstanding importance took place:

1. The organization of a division of industrial hygiene and sanitation by the United States Public Health Service at Washington, D. C., under the direction of Surg. J. W. Schereschewsky.
2. The creation of a section on health service in the National Safety Council, which section held its first session in conjunction with the Fourth Annual Congress at Philadelphia in October.
3. The inauguration of the Section on Hygiene and Preventive Medicine by the American Medical Association, under the chairmanship of Dr. Otto P. Geier.

Many educational institutions readily saw their opportunity and their responsibility in this developing field. Harvard University, however, was the first institution in the world to establish a course of instruction and research leading to degrees in industrial hygiene, in the year 1918. These studies led to the Certificate of Public Health in Industrial Hygiene and to the degree of Doctor of Public Health in Industrial Hygiene. Following these educational curriculums, the school started the *Journal of Industrial Hygiene*, which now occupies a prominent place among journals exclusively devoted to this subject.

A number of state departments of health have established bureaus of industrial hygiene and have attained definite and worthy objectives in this field.

In 1916, a group of industrial physicians assembled and formed the American Association of Industrial Physicians and Surgeons. This professional group has been instrumental in preserving the ideals of medicine in industry.

THE SPECIALTY OF INDUSTRIAL MEDICINE

In the beginning, industry largely felt the need for the services of physicians because of the necessity of treating and preventing injuries. Gradually, however, it became apparent to the industrialist that there was a greater source of economic loss. Industrial physicians themselves soon became convinced not only that they must be able to cover the whole ground of sanitation and safety, spending an hour or two at the plant daily checking up injury cases, but also that there were more important considerations.

The efficient industrial physician of today gets out into the plant from time to time. He makes an adequate study of the conditions under which men work; namely, heating, lighting, ventilation, toilets, lockers, lunchrooms, shower-baths, drinking water, and the places provided for eating. He studies especially the chemical hazards involved in manufacturing processes; the dangers to eyes; the hazards to the skin; the risks of exposure to poisonous gases, dusts, heat, cold and electricity. He likewise recognizes the relative value of physical examinations prior to employment and of periodic examinations during the course of employment. He knows what physical defects exist in his industrial clientele; through a check-up system he is able to supervise the correction of these physical defects; he consults freely with the employment department and with the division of personnel relations, using their expert knowledge on job analysis and placement so that those with permanent physical defects may be placed on work where the effects will be minimized.

Preventive medicine in industry is further emphasized by the giving of first aid to minor illness before it becomes a major consideration. The various complexities and ramifications of mental hygiene in industry are given proper time and consideration, assisting in the establishment of an equilibrium in the important field of human relationships.

THE GENERAL PRACTITIONER

The general practitioner is distinctly an individualist. He deals primarily not with group but with individual problems and reactions. He is, of course, the most prominent figure in community medicine. Without him, millions of people would suffer.

---

[*] From the Industrial Health Division, National Safety Council, Chicago.

[*] Read before the Section on Preventive and Industrial Medicine and Public Health at the Eighty-First Annual Session of the American Medical Association, Detroit, June 27, 1930.

[†] Dr. Marbaker died, March 12, 1930.

Where well directed systems of health supervision in industry have been inaugurated, the general practitioner in the community has found this service distinctly helpful. Diagnostic protocols together with recommendations of procedure are sent to him by industrial groups for his guidance; physical defects are referred to him for correction; chronic diseases which are not considered the responsibility of industry are sent to him for prolonged observation and treatment.

It is easy for the general practitioner to say to the employee who consults him, "You must change your job," without knowing what this involves. The real answer to this situation was given by Dr. Harry Myers some years ago when he said "No doctor has a right to give such advice unless he is willing to go to the plant and personally see just what his patient is doing and under what conditions he is doing it." Contrariwise, it should be said that the industrial physician should not infringe on the rights of the family physician by habitually treating the members of employees' families. More friendly consultations would be desirable.

It should be emphasized that, when the general practitioner renders a service for an industrial employee, he is not necessarily cooperating with the industrial physician but directly with industry itself. He must remember that professional courtesy will be welcomed, however, by the industrial physician.

DEFINITION AND OBJECTIVES

Perhaps the situation can be better understood if the problem is stated briefly. Approximately fifty millions of people are engaged in industrial and mercantile pursuits in the United States, and on their ability to produce rests the progress of industry. The nation will probably continue to increase its industrial activities. Industries and industrial communities will make substantial progress usually in proportion to the care given to the health and efficiency of the backbone of industry —its workers. A well known industrial publication has expressed this point of view forcibly by the phrase "The public health is dependent on the health of a nation's workers."

Some years ago the National Industrial Conference Board defined the industrial physician in these words:

> A physician in industry is one who applies the principles of modern medicine and surgery to industrial workers—sick or well—supplementing the remedial agencies of medicine by the sound application of hygiene, sanitation and accident prevention, and who in addition has an adequate and cooperative appreciation of the social, economic and administrative problems and responsibilities of industry in its relation to society.

The objectives of industrial health practice have recently been stated as follows:

1. To study the health of the employee and help him realize the best health development of which he is capable. This is one of the fundamental principles of industrial hygiene.
2. To protect the worker against contracting disease from another, and also to prevent him from conveying disease to another. This is a basic public health measure and is accomplished chiefly by vaccination and isolation.
3. To study the natural health hazards of the industry and to provide measures for their control. Here accident prevention, first aid to injury and illness, and toxicology come into play.
4. To discover and call to the attention of the employee any defective health habits, especially those of a remediable type, and to assist and encourage the individual in securing proper correction. These procedures are considered to be characteristic of groups most advanced in industrial health work.
5. To enlist the cooperation of skilled medical specialists and organized groups for the correction of defects found among the personnel. This is a common practice among large industrial groups.
6. To provide special and optimum conditions for handicapped persons and to furnish satisfactory supervision for them, especially with regard to proper occupational placement.
7. To provide a dispensary service which will give prompt and efficient attention to slight indispositions, in the attempt to ward off major illness. This is the practice of first aid to illness and has been considered of great economic importance.
8. To instruct the employee how to lead a life of health and, if he is defective, to instruct him how to overcome, as far as possible, the handicap which he possesses. This covers the great field of health education and includes talks, health examinations, posters, health articles, pamphlets, periodic check-ups and the like.
9. To furnish technical guidance and information to all other departments of any given company, with a view of improving the mental, moral and physical status of the group. This includes placement, illumination, ventilation and chemical hazards.
10. To act as a coordinating mechanism on matters of personal health between the company, the employees, other physicians and all other existing health agencies, such as state and city boards of health and state and county medical societies.

THE ANSWER

It is essential that the point of view of the industrialist be understood. He is confronted always by group reactions and problems. He thinks not in terms of individual units but of aggregations. He is also under the burden of economic consideration.

It must also be said that industry, not medicine, initiated the idea that accidents could be reduced to a minimum and that workers are entitled to proper working conditions in which accident and health hazards can be eliminated as nearly as humanly possible.

With these things in mind, what can be done?

The answer is largely one of standards of excellence.

One must go back to the student in the medical school. Curriculums should be so constructed and arranged that the medical student will be exposed to the fundamentals of industrial medicine. Not only must the undergraduate be provided for, but the postgraduate courses should be so correlated and so organized that greater opportunity will be presented for the promulgation of the basic fundamentals of industrial hygiene among established practitioners.

More state and city health commissions should include industrial hygiene in their programs and investigations; county medical societies should more commonly have sectional meetings; hospital staffs should provide clinical material for periodic conferences.

National and constituent medical associations should study the problems with industrialists; through such study, recommendations for standards and procedures could be given officially to industry; liaison arrangements of a flexible type governing relationships of the industrial physician and the general practitioner could be officially recommended.

Ratings should be given to hospitals and clinics where industrial work is carried on.

Finally, to assist the general practioner and the industrial physician further, an official publication of industrial medicine or a section devoted to industrial medicine in a recognized medical journal could be sponsored and maintained.

SUMMARY

The principles, standards, objectives and problems of industrial medicine should be given wider expression through the following mediums:

1. Medical school curriculums.
2. Hospitals and clinics.
3. State and city departments of health.
4. National and constituent medical associations.
5. Official medical publications.

CONCLUSIONS

The physician is and always will be the leading figure in the field of industrial health; as a professional technician he has gained recognition, but as an administrator it must be said that he has not clearly seen his responsibilities or his opportunities.

Industry will not brook dictatorship, but medicine must officially present a united front if it would continue to assume responsibility and leadership in industrial medicine.

20 North Wacker Drive.

ABSTRACT OF DISCUSSION

DR. WILLIAM ALFRED SAWYER, Rochester, N. Y.: Industrial medicine is the legitimate offspring of general medicine and genuine industrial needs; this requires and develops special qualifications. More men are needed who are well trained to do this type of work. Postgraduate training for this field has not borne enough fruit. Just recently I heard the encouraging news that two medical schools have made arrangements to have every member of their fourth year classes spend some time in an industrial medical department. When students are graduated who have had actual experience in such work there will be fewer misunderstandings and more substantial progress. The practice of medicine has been individualistic in the past—in other words, a "one-man-show"; but in view of changes generally, it cannot remain so. Efficiency, service that is adequate and prompt, cooperation, with due consideration to the economics of the situation, are factors of importance in any field of endeavor. The old style doctor, like the old style farmer and the old style corner grocer, worriedly wonders why he cannot make as much money as a good carpenter does. He knows something is wrong, but it seldom occurs to him that his entire professional method may have become antiquated. If industrialists see the trend of the times and work with it, they cannot be blamed. In the light of any serious study of modern science, industrial medicine is inevitable. Indeed, it is only just beginning. All too often the medical profession is caught napping. Lay groups aware of certain needs in community life propose and inaugurate new measures, while organized medicine stands by and offers nothing but destructive criticism. Not once have I heard organized medicine offer a better plan of caring for the health problems of industry. Some form of medical supervision for workers is necessary. Can we not rationalize this situation on some such basis as this: First of all, it must be recognized that far too much *incipient illness* goes undetected and untreated among workers in industry. There is a tremendous waste here, which alert medical men ought to be interested in caring for. Workers will not seek early and timely medical attention, because of the cost. The industrialist has seen this and, with his customary action, has made an attempt to solve it. Medical men have known it for generations but have done nothing. The private practitioner cannot provide adequate diagnosis for the worker for the price the worker can pay. He gives him the best he can. Is there not a chance here for a little team work? Industry can furnish the diagnosis. The practitioner then can utilize these observations to give the worker adequate treatment. This is already the practice in many instances and seems to work to the advantage of all concerned. It is an ideal arrangement. It is the future solution of some of the problems of adequate medical care for all.

DR. G. H. WOOD, Detroit: The statement was made that the difference between the industrial physician and the family physician is that the industrial physician sees and thinks in terms of groups, in terms of masses, while the individual physician sees and thinks in terms of individuals. That is an important distinction. That is just one of the reasons why, in preparing our plans of organization and procedure in industrial medicine, we ought to keep in mind, as our goal, the ideal in the practice of medicine as it has been handed down to us through the ages. The family physician is the one who deals with individual, personal health. That is historic. The industrial physician comes in to handle the mass influences or the group conditions under which the worker spends his working hours. The industrial physician has plenty to do in looking after the light, heat, dust, moisture, poisons and all the various hazards that occur in the hours of industrial employment. When it comes to personal advice as to what the employee eats when he is at home, how long he sleeps, how much he dances, how much he drinks, what kind of liquor he gets and where he gets it, and so on, it may be a matter of dollars and cents to the employer, but I ask the question, sincerely and deliberately, Is it really the employer's business? And, if it is not the employer's business, is it the industrial physician's business? I want to leave these questions with you to answer, yourselves. My personal opinion is that we should be very cautious about invading the relations between the private physician and the individual.

CHOLECYSTOGRAPHY

AN ANALYSIS AFTER SIX AND ONE-HALF YEARS' APPLICATION *

SHERWOOD MOORE, M.D.
ST. LOUIS

The underlying physiologic and radiologic principles of cholecystography have altered little during the six and one-half years since it was first carried out at the Washington University Medical School, Dec. 1, 1923. There have been, however, certain changes in views or detail of methods and other points. It is proposed to discuss these and epitomize the sum of our experience.

Of the substances usable for cholecystography, phentetiothalein sodium -N. N. R. (phenoltetraiodophthalein sodium) is preferred. In addition to being an efficient test of liver function, this dye is less toxic than others. It produces a more desirable cholecystogram with a smaller quantity of dye. The use of substances other than the halogenated phenolphthaleins for visualizing the gallbladder have not proved practical in our hands.

In general, whatever the dye employed in cholecystography, accuracy demands that it be given intravenously, for a known quantity of the substance must reach the circulation if the resultant gallbladder image is to be exactly evaluated.

Routine administration of the dye is entrusted to a single individual of the status of an assistant resident physician. All injections are made at a stated hour. An ample supply of the dye of 8 per cent concentration, in sterile aqueous solution, is ready at hand. After insertion of the needle, a sufficient amount of physiologic solution of sodium chloride is run into the vein to assure that there has been an accurate puncture. By means of a two-way valve, an amount of dye solution is then slowly run into the vein by gravity until the proper quantity for the patient's weight has been administered. Saline solution is then run into the vein to insure that all traces of the dye are completely removed from the blood vessel. We consider 2.5 Gm. of phentetiothalein sodium the proper quantity for an adult of average size (150 pounds, or 68 Kg.). The amount of dye solution given is varied above or below this quantity, according to the patient's weight. We have found that it is desirable to have a greater dilution of the dye than was formerly advocated, because concentration of the latter increased the likelihood of injury to the vein wall. In its mildest form, this event is manifested as a painful sensation in the vein. In the severer cases, there may be a phlebitis. Since the inauguration of the present method there has been a gratifying decrease in the number of disagreeable effects, both local and general, which have followed the intravenous introduction of cholecystographic dyes.

---

* From the Washington University School of Medicine.

* Read before the Section on Radiology at the Eighty-First Annual Session of the American Medical Association, Detroit, June 26, 1930

If oral administration of the cholecystographic dyes is employed, any of the standard methods that will insure the passage of the dye from the stomach into the intestine will be satisfactory. Oral cholecystography in our hands has been employed for diagnostic purposes only in special cases; for example, in those with an obscure abdominal complaint in which radiologic gastro-intestinal examination gives no signs, and in which the symptoms are insufficient to warrant the intravenous procedure. It is occasionally also employed in obese subjects when there is difficulty in finding a vein suitable for puncture. Our experience has been that more subjective discomfort (usually in the alimentary tract) follows the oral than the intravenous administration of cholecystographic dyes. These untoward manifestations are chiefly nausea, vomiting and diarrhea. Vomiting and diarrhea raise a doubt as to whether sufficient dye is absorbed from the alimentary tract to give dependable data as to its concentration in the gallbladder. Phentetiothalein sodium is valueless as a test of liver function when given orally, because the quantity of dye absorbed is unknown.

Table 1.—*Incidence of Reactions in 1,956 Cases of Intravenous Administration of Phentetiothalein*

	Reaction, 666 Cases: 34 per Cent of Total Cases		
No Reaction 1,290 Cases	Mild (First Degree) 385 Cases	Severe (Second Degree) 281 Cases	Third Degree Reaction
66 per cent of total cases	57.8 per cent of total reaction 19.7 per cent of total cases	42.2 per cent of total reaction 14.3 per cent of total cases	None

It is our practice to rate the reactions of cholecystography according to their intensity into three groups, of the first, second and third degree. First degree reactions are those with any subjective sensation which the patient may experience. Second degree reactions are more intense subjective feelings than the preceding, and, in addition, there may be urticaria, giddiness or malaise. Those of the third degree consist of a fall in blood pressure and a tendency to syncope. The reactions in 1,956 consecutive cases of intravenous administration of phentetiothalein sodium are given in table 1.

The intensity and frequency of reaction with other dyes were greater than the aforementioned. Reactions are virtually ignored in intravenous cholecystography, provided the following conditions are fulfilled: The patient should not be too debilitated nor have a low blood pressure concurrent with cardiac or arterial disease.

Cholecystographic estimation of the condition of the gallbladder is based on the fact that the normal organ receives the dye, concentrates it, alters in size (or shape), and finally evacuates its contents. This sequence can be assured only if the organ is at rest during the foregoing cycle. A diseased gallbladder has its functions interfered with, and the departure from normal behavior is proportional to the degree of impairment of the organ. The test reveals anatomic changes only incidentally or inferentially.

The fat meal is not used for testing the emptying capacity of the gallbladder, experience indicating that if the organ is visualized it will empty itself; also, that any impairment of its wall that might affect the organ's ability to void its contents would have as concomitants obvious deviations from the normal cholecystographic behavior.

In disease of the liver of such extent that the gallbladder function is affected, there would scarcely be occasion to attempt cholecystography as the diagnosis would probably be obvious. Obstructive lesions in the ducts of the biliary tract may be placed in the same category and for the same reasons. Obstructive lesions of the cystic duct constitute an exception. In such a case the gallbladder would almost certainly be pathologic, and this diagnosis would be difficult to achieve. It is pertinent at this juncture to state that acute disease of the biliary tract is a contraindication to cholecystography, not because of any inherent danger in the procedure but because an inconclusive finding will almost certainly result from the test in such cases.

There have been instances in which the radiologist considered the cholecystographic behavior normal but in which the symptoms indicated cholecystitis. The microscopic examination of the gallbladder revealed little or no pathologic change. However, grossly, in this and all similar cases there were extensive adhesions between the gallbladder and the adjacent structures; in other words, there was a pericholecystitis. Such cases form a group that will probably always give rise to diffculty in correct cholecytographic interpretation. Mistakes arising from this cause are to be anticipated until such time as the symptoms of disease in the right upper abdominal quadrant are better differentiated into their individual components than is the case at the present time. The preceding prompts the question, What is pericholecystitis, and what are its symptoms? Does chronic pericholecystitis remain confined to the serosa of the gallbladder, or do the remaining portions of its wall ultimately become involved, with loss of function? My experience with cholecystography leads to the conclusion that patients may suffer from what appears to be gallbladder disease, when in truth there is only a localized peritonitis (with adhesions) in its vicinity. The etiology of pericholecystitis has been discussed elsewhere,[1] and it is sufficient to recall here that it originates in two ways, as shown by cholecystographic studies—one from the gallbladder itself, and the other from neighboring structures. In the first (pericholecystitis of intrinsic origin) there is a total absence of the concentrating function of the gallbladder. In the second (pericholecystitis of extrinsic origin) there is an approximately normal concentrating function of the gallbladder, with rarely demonstrable deformity or fixation of the organ. Is extrinsic pericholecystitis a stage in the process of the final and complete loss of cholecystic function such as is the case in the pericholecystitis of intrinsic origin? In the group with pericholecystitis are found all the errors of diagnosis in which the test resulted in normal cholecystograms and operation revealed a pathologic gallbladder. There are ten of these in our operative material. In this series, notes by the surgeon generally refer to extensive adhesions but the pathologic examination reveals little anatomic change except in the serous coat. Pericholecystitis is dealt with at length for the reason that it has many pitfalls in cholecystographic interpretation.

---

Operations	No Operation	Operations	No Operation	Operations	No Operation
25	29	15	28	19	48

* There were 164 preoperative diagnoses of gallstones; 10.46 per cent of total pathologic cholecystograms.

There is a type of stone found in the gallbladder with normal function which is not otherwise discoverable, that is, the so-called negative or cholesterol stone. In such cases the gallbladder can still concentrate the bile, and these stones appear as filling defects which are characteristic in appearance. Such stones have been found on sixty-seven occasions among the pathologic cholecystograms. Nineteen of the patients were operated on, and in all the stones were found. This is a suitable point for a few necessary words as to gallstone radiography. The latter is a test of physical quality, and hence roentgen observations in the case of gallstones, whatever their nature, reveal only certain of their physical properties. It throws no light on their origin, etiology, mechanism of formation or the part that they play in cholecystitis, either as resultants or as causative agents. Reference to table 3 reveals that there were fifty-four examples of gallstones in which no dye was present in the gallbladder, and forty-three in which only a small amount was observed. Needless to say, cholecystography is unnecessary for the discovery of such gallstones. There is this interesting point, however, in the ninety-seven cases of calcified calculi: the concentrating function of the gallbladder was materially affected. In five cases, the concentration of the dye in the gallbladder approximated normal. These five cases are examples of the pathologic gallbladder with normal cholecystographic behavior. Because of the experience with calcified gallstones, radiographic search for them precedes cholecystography. If intra-abdominal calcification unusual in character or location is found, cholecystography may be helpful in reaching a conclusion as to its nature. Pathologic reports from the operations done in 418 cases are proof, if it were needed, that the demonstration of a calculus of either the calcified or the cholesterol type is of small consequence, since 157 gallbladders containing stones have been found in 395 cholecystectomies in which there was no cholecystographic evidence of their existence. This is in strong contrast with the finding of only fifty-eight cases of stones diagnosed preoperatively. The cholecystographic observations of patients with cholelithiasis indicate that the method leaves much to be desired.

Low in the scale of accuracy of preoperative diagnosis is the cholecystogram which reveals a gallbladder with a deficiency of the concentration function, having a "thin" or "faint" shadow. It is in this class of cases that the clinical and cholecystographic opinions most frequently diverge. It is one in which the examiner needs to be extremely wary, if for no other reason than because of the technical variation that may be present in the films. We formerly attached much importance to delay in concentration of the dye and late appearance of the gallbladder shadow or its persistence beyond the twenty-four hour period. Greater experience has led us to place these cases in the general class of deficiency of gallbladder function allied to "thinness" or "faintness" of gallbladder image. The persistence of the shadow beyond the twenty-four hour period is so dependent on food intake and activity that in our view its diagnostic importance has dwindled virtually to the vanishing point.

Up to April 15, 1930, we have had 3,044 cholecystographic examinations, and in 1,567 of them radiographic diagnosis of a pathologic gallbladder was made. Only 406 patients have had operations on the biliary tract. This seems to be a small number of operative cases relative to the total of examinations. However, many of these were made in order to build up experience rather than with the object of establishing a specific diagnosis. Analysis of the reasons for nonoperation in 622 hospitalized patients is shown in table 4. The remaining patients with pathologic gallbladder and who had no operation were ambulatory and hence could not be adequately followed up.

That such a small proportion of the total number of cholecystographic patients was operated on, coupled with the long list of those pronounced normal and not otherwise checked, might in some quarters be considered as indicative of a weakness in this diagnostic method. The normal cases number 1,477. Among them symptoms and clinical evidence have not been strong enough to lead to the opinion that the cholecystographic examination was in error, or that operation was in order, except in ten cases. These have been fully discussed previously in connection with pericholecystitis.

Table 4 may be taken as evidence of one of the weaknesses of cholecystography. This procedure has been stigmatized in several quarters because it was what was designated as a "functional test" in contradistinction to one that reveals actual pathologic anatomy. The function of the gallbladder, as the foregoing series would indicate, may be totally lost and the patient be symptom-free. If he is in this happy state, and so remains, there is no reason to carry out surgical or other treatment.

One might conclude from comparing the tables of the cases in which operations were performed and those in which operation was not performed that the test is of little value because, after all, physical signs and symptoms dictated the method of treatment. Against such an opinion, however, is the fact that the signs and symptoms of diseases of the biliary tract, contrary to general belief and teaching, are most uncertain and inconsistent. Consequently, the evidence of the tables does not materially affect the value of cholecystography.

A word in regard to the relative merits of the oral and intravenous methods of dye administration. What are considered dependable observations, I believe, are secured only in those cases in which the test has been done intravenously. The gallbladder that is promptly visualized, concentrates the dye, and empties without delay in the oral method is a normal gladdbladder. The observations in pericholecystitis, that is, persistent deformity and fixation of the gallbladder, and calculi (this in reality means cholesterol calculi), when found by the oral method, are as dependable as when they are found by the intravenous. Any deviation from this behavior when the oral test is employed, I feel, cannot be relied on, because of the numerous factors influencing the absorption of the dye from the alimentary tract. Such cases should be followed up by an intravenous test.

Table 4.—*Analysis of Reasons for Nonoperation in 622 Hospitalized Patients*

Major illness elsewhere and poor operative risk	321
Operation refused	94
Operation postponed	53
No reason assigned	78
Insufficient clinical evidence of gallbladder disease	54
Medical treatment advised	22
Total	622

Against the thesis that pathologic processes of the gallbladder affect its function of concentration are certain cases which constitute exceptions. Cholesterol stones are observed in cholecystograms because the concentrating function of the gallbladder is more or less preserved. Considering the possible relationship between the formation of cholesterol stones and cholesterosis of the gallbladder, it is quite possible that a considerable number of cases of cholesterosis present cholecystograms which are pronounced normal. Even in the cases in which there are calcified stones, there are five examples in the material presented in which the concentration of the dye in the gallbladder approximated normal. Another example of the pathologic gallbladder which may have a normal concentrating function is found in the group with pericholecystitis. This type of case is the one that I believe gives the largest proportion of the errors chargeable to cholecystography.

CONCLUSION

Intravenous cholecystography is the most accurate method now in use to determine the condition of the gallbladder. Oral application of the test is valuable to prove the organ normal and to determine the existence of cholesterol stones and deformities of the gallbladder. Nonvisualization and faint visualization of the organ with the oral method should be confirmed by an intravenous test. With the intravenous method, the pathologic examintion of excised gallbladders shows a high degree of accuracy for the preoperative diagnosis. Errors in preoperative diagnosis are found chiefly in the cases of pericholecystitis, and possibly in examples of cholesterosis of the gallbladder (there have been no examples of this). In view of the fact that only 58 of 220 cases of stones were demonstrated preoperatively, the percentage is so low that the discovery of stones cannot be thought to be a valuable property of cholecystography. Therefore, a radiographic examination of the gallbladder region should precede cholecystography. Normal cholecystographic behavior can occur with both calcified stones and cholesterol stones, but this behavior is exceptional. It can also occur with extensive pericholecystitis. Such observations are not sufficiently frequent, however, to constitute an indictment of the usefulness of cholecystography in the diagnosis of cholecystitis and its associated pathologic conditions.

Barnes Hospital.

ABSTRACT OF DISCUSSION

Dr. James T. Case, Chicago: I now have given the intravenous Graham test in approximately 5,000 patients and some hundreds with the oral method. I naturally speak from a larger experience with the intravenous method. I noted that Dr. Moore does not continue to use the fatty meal for estimating the emptying time of the gallbladder. I myself continue using the fatty meal, observing the ability or inability of the gallbladder to contract, and especially for the reason that when there are suspicious vacant spots in the filled gallbladder shadow one can speak much more definitely about them when the gallbladder shadow is contracted and its contents more condensed. I have discovered a few patients with a marked delay in gallbladder evacuation, the delay extending to seventy-five or even a hundred hours, in which subsequent events showed that I was dealing with carcinoma of the pancreas or stone in the cystic duct itself—very small gallstones which were hardly palpable. In some of these cases the gallbladder shadow persisted as long as a hundred hours without perceptible diminution and without change in size. I notice that in one of his tables Dr. Moore's percentage of accuracy of diagnosis of pericholecystitis is rather high; as given in the table the accuracy was 95 per cent. I was rather surprised myself in going over some of my own operative cases to realize that the percentage of correct diagnosis of pericholecystic adhesions was high. I think I may say that pericholecystitic adhesions are suggested by a gallbladder outline of irregular nature or by displacement with fixation when the displacement is not suggested by some extrinsic lesion. Sometimes the pressure effect of some adjacent organ can be seen. Inability of the gallbladder to empty itself often suggests pericholecystitic adhesions. The percentage of stones found in my cholecystographic series is higher than Dr. Moore's. I am at a loss to figure out the discrepancy. In my previous work I have spoken of "absence of shadow," "stone positive," in which stones were evidently present by nonopaque areas, "normal cases," and then a fourth group, which is called "pathologic, noncalculous," because experience shows that they were essentially noncalculous. In 121 cases that were reported "pathologic, noncalculous" on that basis, six cases of stones were found at operation. That is an error of a little less than 5 per cent. I included in that series thirty-six cases of "normal," eighty-five cases in which I said the gallbladder was "pathologic, noncalculous." I based that pathologic and noncalculous opinion on deficiency of the concentrating function, as shown by a faint shadow, or irregular contour of the gallbladder suggesting adhesions, or marked delay in emptying of the gallbladder or some combination of these.

Dr. B. R. Kirklin, Rochester, Minn.: I am satisfied that the criticism of the results obtained generally with the oral method is due to the technic that is used in applying this method. My own results were not entirely satisfactory until I adopted the technic that I use at the present time. If one checks carefully the results obtained by the men using the oral method and compares them with those obtained by the use of the intravenous method, I am sure that there is little difference. At the Mayo Clinic the following technic is used: Each patient receives 4 Gm. of tetiothalein sodium (N. N. R.) dissolved in 1 ounce (30 cc.) of distilled water. It is important that the aqueous solution of this drug is not more than twenty-four hours old; therefore, the individual doses should be prepared each day. The following instructions are given to the patient with the dye: "1. At 6 p. m. eat supper of usual amount, but avoid eggs, cream, butter and other fats. 2. At 7 p. m., or immediately after supper, empty entire contents of this bottle (the dye) into a glassful of grape juice, stir well and drink all. 3. Do not take a laxative. 4. At 7 a. m. the morning of the test take a rectal injection of warm soap suds until the water returns clear. 5. Do not eat breakfast; you may drink water, black coffee or clear tea." I am convinced that better results are obtained with a full evening meal than with a light meal, and also that the best shadows result when the dye is taken shortly after supper rather than two or three hours later. Cholecystograms are made at fourteen and sixteen hour periods, and again at twenty hours, after the patient has taken a glass of half milk and half cream with his lunch. A Potter-Bucky diaphragm is used for all gallbladder work, with a standard exposure of from one-half to one second, with a 26-inch target film distance, the kilovoltage being varied according to the thickness of the patient. It is essential to keep the exposure time as short as possible in order to eliminate the slightest movement of the patient; otherwise gallstone shadows may be completely blotted out. My experience is in accordance with that of Dr. Moore; namely, that the normally functioning gallbladder is the least reliable finding that there is in cholecystography. Even with the oral method I have found a higher percentage of diseased gallbladders that function normally than he is reporting with the intravenous administration of the dye. I am reluctant to attempt to diagnose or exclude pericholecystic adhesions.

Dr. Sherwood Moore, St. Louis: Though it has been tried in our clinic, oral cholecystography has not been satisfactory. Possibly this is our own fault. Neither cholecystography nor the treatment of cholecystitis is to be entered on lightly, and we feel that, in both, absolute accuracy is essential. I appreciate that Dr. Kirklin is in the same position as regards accuracy. We feel that the necessary accuracy can be secured only with the intravenous method of cholecystography.

The Antiquity of Disease.—From the researches of Rudolf Virchow, the father of paleopathology, Bernard Renault, Roy L. Moodie and others, it has been demonstrated that the history of disease properly begins with the early Paleozoic or Proterozoic, 100,000,000 or more years ago. The fossil remains of primitive vertebrates of the Paleozoic era have yielded abundant evidences of such diseases as dental caries, pyorrhea alveolaris, osteomyelitis and fracture, diseases which apparently have changed but little, if at all, in the past 100 million years. As examples may be mentioned the fact that caries has been found in the bones, scales and teeth of fishes from the Permian period in France; the mandible of a three-toed horse shows caries which resulted in absorption of the alveolar margins and exposure of the roots of the teeth, i. e., the sequence of events which may occur in pyorrhea alveolaris as we know it today; and caries of Pleistocene elephants has been noted. One of the most interesting facts of recent development is that arthritis deformans, a disease found in so many Egyptian mummies, is identical with the "cave-gout" (Höhlengicht) which Virchow, in 1870, reported in bones of a Pleistocene cave bear.—Oliver, W. W.: Stalkers of Pestilence, New York, Paul B. Hoeber, Inc., 1930.

SPRUE

SOME POINTS ON ETIOLOGY, DIAGNOSIS, AND ESPECIALLY TREATMENT *

ANTHONY BASSLER, M.D.
AND
J. RAYMOND LUTZ, M.D.
NEW YORK

For a time it looked as if the etiology of sprue had been settled by Ashford[1] in *Monilia psilosis.* Subsequent encounters with cases of true sprue in which this yeast was not found although careful laboratory technic was followed in the examinations of stools, including the improvements and modifications, leave the disease, originally described by Hillary of Barbados in 1776, in its etiology gracefully suspended between doubt and question.

Especially confusing are the instances of the irregular presence of *Monilia psilosis* at different times in the same case, a long period of its absence, the clinical symptoms and conditions, and the typical character of stools showing no change. D'Herelle[2] deduces from bacteriophagic work with stock antidysentery strains adapted to the Flexner and Hiss *Eberthella paradysenteriae* that the main causative, or at least the contributory agent of this disease is, as Morison and Martin suggest, a paradysentery bacillus.

Sprue, an adult disease, found practically always among white people, and encountered twice as often in women as in men, a problem in diagnosis in the early stages and the atypical cases, and simple in the typical cases, still works its havoc in many parts of the world. In the countries in which it is most often seen the people are as much alarmed at sprue as at carcinoma. One needs but to handle enough individuals from such quarters of the globe as Cuba, other West Indian Islands, Central America and the northern countries of South America to realize this.

In the cases with slow and insidious onset (about one third of all cases), mistakes in diagnosis are commonly made. When the onset is that of a severe type of digestive disturbance with continued diarrhea, especially in the morning, sprue should be suspected; and when this is present with loss of weight, sallow complexion and anemia, mouth symptoms (present in about three fourths of the cases) and the characteristic bowel discharges, the diagnosis is comparatively easy. Not infrequently, however, diagnosis of "beginning sprue" or "near sprue" and the like is made when other reasons for the diarrhea are the cause. Among these are instances of *Ameba histolytica* infections, bacillary dysentery, more particularly the chronic forms represented in ulcerative colitis, digestive and neurologic diarrhea and biologic intestinal toxic states with irritable colons. Because a person in a warm climate where sprue is endogenous and the people are fearful acquires a more or less continued diarrhea, he should not be taken advantage of by vague diagnoses of sprue. In these countries are found most of the diarrheal disorders, and these other diarrheal diseases and disorders should always be thought of before sprue is mentioned.

---

* Read before the Section on Gastro-Enterology and Proctology at the Eighty-First Annual Session of the American Medical Association, Detroit, June 26, 1930

[1] Ashford, B. K.: Am. J. M. Sc. **154**: 157 (Aug.) 1917.

[2] D'Herelle, Felix: Bacteriophage and Its Clinical Applications, 1930, p. 196.

It is believed that appropriate and timely treatment cuts short the incidence of chronic sprue in about one third of the cases, this being mostly a matter of dieting. Since diet, whether milk, high protein or fruits, is lacking in results in the chronic case, there is some question as to whether in instances of recovery, the cases were really controlled by diet or a natural recovery was accomplished. There is agreement, however, that dieting is always in order in the acute and subacute case. It is believed that in at least two thirds of the chronic cases no benefit is derived from any kind of dieting or other types of treatment, although here and there, if dieting is kept up for six months or more benefit is sometimes seen. Even here, as in the acute and subacute cases, it may be that the disease runs itself out irrespective of dieting. The rate of mortality is high, as much as 80 per cent in the chronic forms, and it is this, with the liability of chronicity, that has caused dread of the disease among the people of these warm countries.

The present article pertains to treatment rather than to diagnostic problems, and it is based on the results accomplished in ten consecutive cases of sprue, the results being gratifying enough in our opinion for report. These comprise essentially four methods of treatment: (1) high liver diet (with or without excess vitamins); (2) transduodenal lavages; (3) correction of an intestinal infection, and (4) living for a time in colder climates. These are stated in what seems to us the order of their relative importance.

Blood transfusions, injections of iron preparations, and the types of diets formerly in use did not produce worth while results in our hands. When Minot and Murphy[3] advanced the employment of liver diets for pernicious anemia, the blood pictures found in sprue together with the frequent presence of achylia gastrica suggested the use of a similar diet in sprue to us in December, 1920. The value of the diet was more or less confirmed later by Ashford,[4] Williams,[5] Holmes and Starr,[6] Smith,[7] Baumgartner and Smith,[8] Reed and Ash,[9] and Porter and Rucker.[10] In all the suggested diets, liver was taken as food, and not in the form of extracts. The type of diet generally employed was as follows:

Calf's or beef liver cooked in any form, taken in at least one or two meals every day, the day's quantity being from 120 to 240 Gm. (4 to 8 ounces) cooked weight. An equal amount of lamb's kidneys may be substituted for the liver, entirely or in part.

Considerable liver sausage, blood sausage, and the marrow from grilled or roasted long bones that have been split, the marrow to be eaten with salt and pepper spread on toast. The sausage may be fried. One of these foods should be partaken of each day. In addition, 120 Gm. (4 ounces) of beef or mutton muscle (meat), cooked in any way, should be taken daily.

No less than 300 Gm. (10 ounces) cooked weight of the following vegetables (especially lettuce, lentils and spinach): lettuce, cucumbers, spinach, asparagus, rhubarb, endive, marrow, some sauerkraut, beet greens, dandelion, Swiss chard, celery, tomatoes, Brussels sprouts, watercress, okra, cauliflower, egg plant, cabbage, radishes, leeks, string beans, broccoli, olives, pumpkin, turnip, kohlrabi, squash, beets, carrots, onions, mushrooms, cranberries and lemons.

Each day from 250 to 500 Gm. (8½ to 17 ounces) of fresh fruit, especially bananas, apricots, strawberries, pineapples, oranges and grapefruit.

The equivalent of 45 Gm. (1½ ounces) of fat from butter and fresh cream (there is 16 per cent of butter fat in cream that settles in milk bottles, and 40 per cent in the XXX or heavy whipping cream). The cream may be added to any food or taken as suits the patient.

If desired, an egg each day and several glasses of milk. In addition to the foods mentioned, bread, especially dry and crusty, potatoes, and cereals in abundance so that weight is kept up or added.

Sugar, which may be taken in small quantities; but very sweet foods are not allowed.

When practicable, additions were made to the vitamin contents as follows: cod liver oil in doses of from 4 to 10 cc. for vitamins A and D; orange, pineapple, and fruit juices were increased for A, B and C; yeast, peas and lentils for B; tomatoes, lemon juice, oysters, apples and bananas for C; and lettuce, milk and fats for E.

Transduodenal lavages with hypertonic saline solution of 9 Gm. each of sodium sulphate and sodium chloride in 1,000 cc. of water at 104 F. was used before bedtime to clear out the fermenting food residue of the day's meals. As a rule the quantity introduced was rarely over 500 cc. and was conditioned by the number of bowel movements produced and the general state of health. As improvement took place, these were employed less frequently or the quantity of solution was reduced.

The removal to colder climates was only partly practicable. Most of our patients came under observation in the summer months when the weather in New York was warm, and those requiring active treatment had to remain in the city for a time before going away to the northern parts of the country. Those that could be sent to the mountain regions or to Canada at once were sent with nurses, usually to places where blood counts could be made.

When distinct benefit had been established, biologic studies of the feces were made and when a definite infection of the dysentery, paradysentery, *Salmonella*, *Eberthella* or *Escherichia* forms were present biologic treatment with rectal or subcutaneous vaccines or antagonisms for the control of them were used. This, as previously suggested, is at times the least, and at other times a most important item for complete results in recovery, depending usually on the pathogenicity of the infecting organisms.

All the cases were handled in the foregoing ways with modifications here and there, and of these the following brief reports are offered:

REPORT OF CASES

Case 1.—Mrs. A. G., from Havana, had symptoms of cramps, vomiting, morning diarrhea, loss of weight, sour regurgitation, glossitis, and anemia, of one year's standing. The stools, though characteristic of sprue, were negative for *Monilia psilosis; Oxyuris vermicularis* was present. She was given two months' active treatment. The blood count rose from 2,280,000 red blood cells with 65 per cent hemoglobin to 4,800,000 red blood cells with 80 per cent hemoglobin. The last count was sustained. The patient made a complete recovery.

Case 2.—Dr. A. P., from Bogota, Colombia, had symptoms of morning diarrhea with remissions, loss of weight, progressive weakness, tremors and aphthous ulcers, of four years' standing. The stools were characteristic of sprue but negative for *Monilia psilosis*. Several blood transfusions were necessary. Three months' active treatment was given, during which time the blood count rose from 1,800,000 red blood cells with 35 per cent hemoglobin to 4,800,000 red blood cells, with 70 per cent hemoglobin. The last count was sustained. His recovery was complete.

Case 3.—Captain J. C., United States Army, was stationed for three years in the Philippines. He developed symptoms of diarrhea, indigestion, loss of weight, progressive weakness and sore mouth, which continued for three years. At examination, the stools were found characteristic of sprue but negative for *Monilia psilosis* and positive for *Endameba nana, Chilomastix* and *Bacillus enteritidis.* He was given two months' active treatment and three months' biologic treatment and was in Canada for six months. His blood count increased from 2,100,000 red blood cells with 42 per cent hemoglobin, to 4,850,000 with 77 per cent hemoglobin. He made a complete recovery.

Case 4.—Dr. R. P., from Puebla, Mexico, had symptoms of loss of weight, morning diarrhea, glossitis, anemia and excessive flatus, of two years' standing. The characteristic stools were positive for *Monilia psilosis,* other types of yeast, *Trichomonas intestinalis, Salmonella para-aertrycke* and *Streptococcus hemolyticus* II. Active treatment was administered for seven weeks and biologic treatment for six weeks; no climatic treatment was given. On examination his blood count was 2,900,000 red blood cells with 46 per cent hemoglobin, and rose to 4,740,000 red blood cells with 82 per cent hemoglobin. The patient reports that he has occasional diarrhea (this I do not think is due to sprue); his general health is good.

Case 5.—A. P. St. J., a man, from Porto Rico, had symptoms of morning cramps and diarrhea, anemia, loss of weight and progressive weakness of nine months' standing. The somewhat characteristic stools were negative for *Monilia psilosis,* but ova were found that resemble *Macrostoma mesnili.* The patient was given nine weeks' active treatment, during which time the blood count increased from 3,200,000 red blood cells, with 64 per cent hemoglobin, to 4,700,000 red blood cells with 92 per cent hemoglobin. The immediate result was good but there was a return of moderate symptoms one year after returning home. He resumed treatment in Porto Rico, with benefit. No blood data on the relapse were available. The patient has now been well for three years.

Case 6.—Mrs. C. S. J., from New Orleans, presented symptoms that indicated sprue. The only time she had been out of the United States was while on a cruise to the West Indies, three years before the symptoms began. The symptoms were sore and red tongue with aphthous ulcers, morning diarrhea, loss of weight and strength, sallow complexion and anemia of nine months' standing. The characteristic stools were positive for *Monilia psilosis* and *Streptococcus pyogenes.* Active treatment was administered for three months; no biologic treatment was given, but climatic treatment was given for three months. On examination the blood count showed 2,250,000 red blood cells with 52 per cent hemoglobin and rose to 4,300,000 red blood cells with 84 per cent hemoglobin. The patient made a complete recovery.

Case 7.—St. J. M. C., a man, from San Domingo, Hayti, had symptoms of morning diarrhea, loss of weight from 171 to 87 pounds (78 to 39.5 Kg.), anemia, sore tongue and progressive weakness for five years. Several types of dietetic and medicinal treatments had been employed without avail. The patient had had blood transfusions and hundreds of hypodermic iron injections. On two occasions intravenous injections of arsphenamine were given, and after each he became markedly worse in a symptomatic way. This was probably due to the fact that arsenic is contraindicated in sprue. The patient was near death. Dieting and lavaging could not be carried out to any extent on account of steadily present nausea and vomiting, and such as was possible was of no avail. The patient died three weeks after returning home.

Case 8.—Mrs. J. A. P., wife of a physician in Havana, had symptoms of loss of weight, anemia, more or less steady diarrhea and sallow complexion, persisting for two years. On examination the stools were found to be characteristic of sprue and positive for *Eberthella paradysenteriae. Monilia psilosis* was present on and off. Active treatment was given for three months, biologic for ten weeks; no climatic treatment was given. The blood count rose from 3,200,000 red blood cells with 70 per cent hemoglobin to 4,400,000 red blood cells with 79 per cent hemoglobin. The patient had a relapse one year later but the symptoms were quickly controlled by short dietetic and lavage treatments. She is now well after two years.

Case 9.—Miss A. T. M., from Georgetown, British Guiana, presented symptoms of indigestion, sour eructations, rather steady diarrhea, loss of weight and strength, insomnia, headaches, and multiple neuritis, which had been present intermittently for two years. The characteristic stools were positive for a yeast that could not be identified as *Monilia psilosis,* and positive also for *Trichomonas,* biflagellates (*Cercomonas*), and *Pasteurella trevisan.* Active treatment was administered for fifteen weeks, biologic treatment for three months; no climatic treatment was given. The blood count rose from 3,400,000 red blood cells with 62 per cent hemoglobin to 4,500,000 red blood cells with 79 per cent hemoglobin. The last count was sustained. The patient made a complete recovery.

Case 10.—Mrs. J. A., from Para, Brazil, had symptoms of morning diarrhea, loss of weight, anemia, intestinal flatus, occasional blood in the sputum and the urine, purpuric spots and a few aphthous ulcers at times. These symptoms occurred in two periods, the first nine years previous, which cleared up on a diet of milk and fresh fruit in three months; after an interval of six years, the symptoms recurred and were steadily present for two years and nine months. The stools were moderately characteristic of sprue, *Monilia psilosis* was present, also a few unidentified ova; the culture was positive for *Clostridium alcaligenes.* Active treatment was given for seven weeks; biologic for four months; no climatic treatment was attempted. The blood count increased from 3,100,000 red blood cells with 47 per cent hemoglobin to 4,700,000, with 81 per cent hemoglobin. The last count was sustained. The patient's recovery was complete.

COMMENT

Differing from true pernicious anemia, in which relative recovery up to 4,000,000 erythrocytes on liver diets occurs in as many as 70 per cent of the cases, and improvement to this figure and then a drop again in 20 per cent, all but one of our cases showed marked improvement in erythrocyte counts and hemoglobin in a short time. Differing from the result in pernicious anemia, too, improvement was sustained on a lower intake of liver, and for long periods of time. It is probable that whatever causes sprue produces the same disturbance in the hematopoietic system as takes place in true pernicious anemia, and that while there may be differences clinically, none can be discerned, even though in pernicious anemia the stomach may show atrophy and the intestine but little or none, while in sprue the main atrophy is in the small intestine. In view of the improvement of the blood on a high liver diet in sprue, it is strongly suggested that the diet acts in a reconstructing and combative way. At least as the blood picture improves, weight, strength and appearance improve with it, as do also the diarrhea and mouth symptoms. It was interesting to note that the well known eosinophilia often produced in about four weeks on liver diet in pernicious anemia may run as high as 70 per cent in these cases of sprue. In this connection, of course, the common presence of intestinal parasites must be taken into consideration.

In the treatments used it was impossible to value the benefits due to the transduodenal lavages. All that we can report is that apparently the digestive symptoms are controlled more quickly with them than without them, this being distinctive in the morning diarrhea, the gastric symptoms, and the clearing up of the intestinal parasites, ova especially.[11] As has been suggested, care must be taken not to be too vigorous with transduodenal lavages in the much reduced case. After the active treatments, a sojourn in colder climates seems to have a substantial effect on recovery, this being important since all but one of these patients had to return to their homes in the warm countries. Sprue commonly robs the intestinal canal of the restrictive *Escherichia* types of organisms, and permits infections by pathogenic organisms to occur or continue there. Since many of these organisms are capable of producing pathologic changes in the intestinal mucosa, an interest in this factor of the disease is also necessary. The cases should be kept under observation until full recovery of the mucous membranes has taken place, the stools contain sufficient bile and are formed, weight is gained, the anemia has improved, and the symptoms have cleared and remained so for at least six months. In the reconstruction, rest, sunshine and fresh air are of value.

---

[11] Bassler, Anthony: Diseases of the Intestine and Lower Alimentary Tract, ed. 3, Philadelphia, F. A. Davis Company, 1920, chapter XVII.

CONCLUSIONS

The etiology of sprue is still doubtful. There is reason to believe that more important than *Monilia psilosis* are states of dysfunction in the small intestine and stomach which cause hematopoietic changes. In these cases chronic bowel infections and climatic factors are important.

The diagnosis of sprue is largely still a clinical matter, but care must be taken to eliminate and evaluate all other causes of disorder before the diagnosis is made.

Excepting in definite cases, on account of fears of the disease, care should be taken not to mention any terms in which the word "sprue" is used, and such terms as "beginning sprue," "near sprue" and "atypical sprue" should be discontinued.

All of our cases presented an anemia of the megaloblastic type, the type that responds most pronouncedly to liver therapy. Up to the present we have seen no instances of what we believed to be sprue without considerable anemia, although nonanemic cases have been reported, and even fatal ones. At the present time it is our belief that sprue without some anemia may be an instance of mistake in diagnosis of sprue.

Although the low carbohydrate diet has been of distinct service, the additions of liver and vitamins enhance its value. Blood transfusions in our experience have been disappointing.

In treatment, the best plan is the combined one of high liver diet with fruits, vegetables and milk product additions, transduodenal lavages, biologic intestinal treatments, and residence in colder climates.

Similarity of the response of the sprue cases on this type of dieting to that of pernicious anemia is noticeable, excepting that the proportion of success is higher and the results more substantial than in pernicious anemia.

In ten cases of sprue here reported, results from treatment were successful in all but a lethal case, one too far advanced for carrying out treatment or expecting a response.

784 Park Avenue.

ABSTRACT OF DISCUSSION

Dr. Damaso de Rivas, Philadelphia: The specific cause of sprue still remains in the domain of theoretical speculation. The question naturally arises whether this disease is but a final symptomatic manifestation of secondary complications of one or several of the well known disorders of the intestine. Careful examination often shows the presence of some parasitic or other diseases of the intestine or internal organs, the timely and proper treatment of which is commonly followed by recovery. I have been surprised to find that sprue is rather a less common disease than is generally believed. The question naturally arises as to the rôle the parasites may have had in the pathology and symptomatology of the disease. Not uncommonly, however, in spite of the most careful study of the case, no definite biologic causes, organic or metabolic disturbances, can directly or indirectly be traced as responsible for the manifestation of the symptoms of sprue. A case that came under my observation clearly elucidated the fact that a definite diagnosis of sprue should not be made without *a priori* taking into consideration the history of the case, the biologic factors and the organic and metabolic disturbances that may give rise to the symptoms common to sprue. A man, aged 55, presented most of the common symptoms of sprue. The diagnosis of sprue was made by several specialists and he was treated accordingly, but without improvement. Three years before he came to Philadelphia he had a gastro-enterostomy for suspected gastric ulcer. After the operation he gradually became weak, anemic and emaciated, in spite of a good appetite, accompanied by marked gastro-intestinal disturbances. A careful examination failed to show any pathogenic bacteria or fungi, or protozoan or metazoan organisms in the intestine. The patient was placed on a regulated diet. He received several intravenous injections of iron and arsenic, blood transfusion, and transduodenal and colonic lavage without improvement, and he died in four weeks. The autopsy revealed a most unexpected and interesting condition. The fundus of the stomach was communicated to the transverse colon; in other words, the surgeon had performed a gastrocolostomy instead of a gastro-enterostomy, which explains the subsequent impairment of nutrition, gastro-intestinal disturbances, anemia, and other symptoms simulating sprue.

Dr. Seale Harris, Birmingham, Ala.: Sprue is unquestionably found not infrequently in the southern section of the United States. It has been found also in England and Germany, in patients who have never left those countries. There are a great many improper diagnoses of sprue. I have seen cases in which the symptoms ordinarily would have been called those of sprue, if one had not known there were other factors in the case. The best work on sprue has been done by Bailey K. Ashford of Porto Rico. He has had a larger experience with the disease than any one else. Yet, at the same time I am not convinced that *Monilia psilosis* is the sole etiologic factor in sprue. Wood of Wilmington, N. C., some years ago did an excellent piece of work in studying pernicious anemia, sprue and pellagra, and he came to the conclusion that *Monilia psilosis* might be the cause of all of them. He isolated *Monilia psilosis* in a number of cases of true pernicious anemia. I have seen cases of pernicious anemia that had exactly the same symptoms as sprue, and the same is true of pellagra, particularly the so-called pellagra sine pellagra. In sprue it is just as important to give large doses of dilute hydrochloric acid when there is achlorhydria, as in cases of pernicious anemia; and a well balanced diet is of great importance in the treatment of sprue. Then there is the question as to vitamin deficiency; in fact, many believe that sprue is a vitamin deficiency disease. A high carbohydrate vitamin deficient diet is certainly a predisposing factor in sprue. There have been many fad sprue cures in various parts of the world, for instance, the strawberry cure, giving largely strawberries, as is in vogue in India and China. In New Orleans, they have the banana cure. They give ten or fifteen bananas a day and nothing else for a few days and they claim that the sprue patients get well. I think the important thing is to regulate the diet of the patient and treat the patient as well as the symptoms. Apparently sprue is not as serious a disease as it is generally considered to be. Ashford reports less than 10 per cent of deaths in 2,500 cases. Why is sprue so prevalent in Porto Rico, why is it occasionally seen in Cuba, when in the Central American countries of the same latitude it is a rare disease? There is a lot to be learned about sprue. Liver extract will control pernicious anemia in a sprue patient just as well as the liver diet.

Dr. Jackson Blair, Cleveland: The digestive tract disturbances, the achlorhydria often present, and the anemia and leukopenia link sprue closely to pernicious anemia. It has been my experience in pernicious anemia that these patients have a chronic mild urinary tract infection that has persisted for years. I have presented a series of cases and evidence that the mechanism of the anemia and leukopenia of pernicious anemia is the chronic loss of leukocytes from the body and an exhaustion from the body of the hematopoietic substance required in erythrocyte and granulocyte formation, both processes of which occur in the bone marrow in the adult. In view of the obvious intestinal lesions of sprue and the evidence of Manson and Bahr that in the ulcers in the lower ileum and colon the mucosa in places is entirely destroyed and replaced by a structureless substance enclosing leukocytes, I present the hypothesis that some of the secondary symptoms of sprue, particularly the anemia, leukopenia and possibly other symptoms, are due to the chronic secondary infection of the intestinal tract and the resultant chronic loss of blood, particularly of granulocytes. There is little doubt that the yeasts and mycelia or *Monilia psilosis* are the primary invaders and may be directly responsible for the diarrhea and certain other symptoms, but it is probably the secondary invaders that are responsible for the greater part of the clinical picture.

Dr. Walter A. Bastedo, New York: Dr. de Rivas indicated that sprue is scarce. Perhaps it is, but this month in New York I saw my seventy-seventh case. Possibly the reason it is scarce is that it is not recognized. Sprue is not the same as pernicious anemia. In our cases and in Dr. Ashford's cases there has been gastric achylia in about 33 per cent. The large majority of even the fatal cases do not present gastric achylia. I have had three or four hundred cases of pernicious anemia. Dr. Mussey of Tulane University has called attention to the scarcity of pernicious anemia in the tropics. A lot of pernicious anemia is seen in the North but not many cases of sprue. In sprue the diarrhea and the sore tongue frequently alternate, and I have had patients who, on being put on the fruit diet when they had the diarrhea, lost the diarrhea in a few days, but then began to get sore tongue so that they could not take the fruit diet, and then diarrhea would come back. It is a most astounding clinical experience to have a severe diarrhea cease when the patient takes large quantities of fruit. Many years ago through the kindness of Dr. Simon and Sir Aldo Castellani there was a patient in our hospital from New Orleans who did not do well. But at the time we had in the hospital two children with celiac disease, which resembles sprue closely. One of the specific treatments for celiac disease is bananas, and through fresh ripe bananas, the patient improved sufficiently to return to New Orleans. I wrote the doctors about the banana idea and later they reported that she had taken eight bananas a day and had gained 40 pounds. Bananas are good and strawberries are particularly good, but almost any fruit will do. Another thing is that these cases occur in the better classes and in the cities. They are not found among the poor of the country districts. Sprue patients almost invariably take low amounts of protein. Many of them have never cared for meat and, probably because of conditions in the tropics, have never had eggs or milk to any extent. I strongly believe that the treatment should not be a fad treatment and I favor milk at the outset and later a good mixed diet with plenty of vitamins, fresh fruit and, if possible, liver. Sore tongue may require a blander diet for a time.

Dr. Frank Smithies, Chicago: Sprue is fairly common, particularly since so many Porto Ricans or Filipinos began to come here for education. I want to emphasize, too, that it is never pernicious anemia. Except as a terminal affair, I have never seen instances of sprue when there was a continuous and permanent achylia, either gastric or pancreatic. Next, the blood is entirely different. It does not run the characteristic relapses that pernicious anemia does, and, most important of all, one never gets in the urine the blood derived pigment, as one finds in cases of true pernicious anemia. The neurologic picture is largely a psychologic picture. One never finds the changes in the central nervous system, as one does in nearly 70 per cent of even early pernicious anemia. I am rather upset by Dr. Bastedo's statement that this is not a disease common among the poor people. I have traveled in tropical and subtropical countries. I have always associated sprue with poverty. The poor natives live largely on little cakes made out of meal. This food during and after cooking is constantly exposed to dust infections of all kinds, and one gets the idea that in sprue he is dealing with a disease of poverty where there is a definite food imbalance. The meal is often dirty. Similarly, when the missionaries (and those are the main group that I have seen) come to tropical climates, the heat suggests to them that they must not eat meat or fats or substances of that kind; rapidly they take up a diet similar to that of the natives, in consequence of which they get the same type of dietetic imbalance, plus tropical infections. If primarily absent, hydrochloric acid comes back nicely in these cases and the individual enjoys fair health, but I have never seen a single patient with real sprue who made a complete recovery and through the remainder of life was a perfectly healthy individual. The ailment leaves organic changes in the heart muscle, in the liver, in the pancreas, and in the muscular wall of the alimentary tract.

Dr. Walter A. Bastedo, New York: As Dr. Smithies referred to my remarks about the poor people, I want to say that that information came directly from Dr. Ashford, who has had some 2,500 cases. He particularly laid stress on the fact that the poor people of Porto Rico are not the ones that have the sprue. The same statement has been made to me by Havana physicians who see a large number of cases.

Dr. Frank Smithies, Chicago: Ashford is an eminent specialist in a larger city and the people in the poor towns do not get to him. They cannot pay his fees. The people in the bushes are taken care of by the missionary doctors with limited facilities and frequently of limited experience, as those people are very poor. I have seen some of Ashford's patients.

Dr. Max Einhorn, New York: I had some patients sent to me diagnosed by Ashford himself and here, strange to say, in one case I found just the opposite picture to the other, that is, with regard to the functions of the stomach. In one there was hyperchlorhydria and also signs of a duodenal ulcer, and in the other achylia, and they were relatives. The two came at the same time and both were sent by Ashford. I treated them on general principles and both were benefited. My impression is that sprue as such, and I have seen a great many of these cases (I have not seen the poor people because they do not come here from Porto Rico and Santo Domingo) is a deficiency disease. There are some things missing. In regard to the pancreatic difficulty, which has been assumed to exist in a great many people, they show also hyperchlorhydria, and in several patients I have found that there is not only a normal function of the pancreas but hyperactivity. I have measured the amount of pancreatic secretion through the duodenal tube, and in one case it was combined with diarrhea. I thought I could ascribe the diarrhea to the irritation through too high activity of the pancreas and that by giving atropine and things contrary to the other things we would achieve improvement.

Dr. Anthony Bassler, New York: I agree with Dr. Einhorn that the deficiency factor is of great importance in the control of the symptoms. Any one who has done some autopsies in cases of pernicious anemia and cases of sprue would be struck with the differences that exist between these two conditions. While there may be a similarity in the blood, that is the only similarity that exists, and even in that, in pernicious anemia, there are certain types of blood pictures never seen in sprue, and I agree perfectly with Dr. Bastedo and with Dr. Smithies that there is a difference in these two conditions. The diet is essentially a fruit-carbohydrate diet. It comprises all that has been best so far in the handling of sprue from various quarters of the globe, and to this is added the high liver content and the use of bone marrow. I have seen a case in which there was a hyaline degeneration both of the islands and of the acinous portion of the pancreas and with that an almost total atrophy of the mucosa of the stomach and the mucous membrane of the small intestine almost to the valve, the mucosa of the intestine being practically blanched white. There is one thought I want to express that was not reported in the series here. I have had twenty-seven patients from various parts of the Southern countries, in whom a diagnosis of sprue had been made, some of them without any diarrhea, some with only a simple anemia, some who never had a sore tongue, others in whom the progressive weakness did not appear and yet a definite diagnosis of sprue had been made. I might add to what Dr. Einhorn has said that some of those patients had been at the School of Tropical Medicine in Porto Rico. As Dr. Smithies suggested, the psychologic side of the patient should be considered when the term sprue is used, because the people down there are fearful of it. I think it is most unfair, if other causes for the diarrhea or the other conditions that may simulate sprue clinically are the cause of the condition in the patient, to use the term "sprue."

PROGRESS IN THE ROENTGENOLOGIC DIAGNOSIS OF DIAPHRAGMATIC HERNIA *

ALEXANDER B. MOORE, M.D.
AND
B. R. KIRKLIN, M.D.
ROCHESTER, MINN.

A vast and growing literature on diaphragmatic hernia, larger than the incidence of the condition would seem to warrant, attests a keen interest in this condition. Once rated as extremely rare, it is now considered more often among diagnostic alternatives because of the publicity it has received and the increasing frequency with which these hernias are being discovered. For example, as late as 1924 it was estimated that in all not more than 1,200 cases had been recorded, but these consisted chiefly of gross and easily demonstrable hernias, and since that time, besides numerous single case reports, several extensive series comprising less obvious cases have been added. When this estimate was made, only twenty cases had been listed at the Mayo Clinic, but during the last six years ninety additional cases have been observed in this clinic alone. It is evident, therefore, that diaphragmatic hernia is not merely a pathologic oddity but a lesion which should be taken into practical account and given higher rank among the possibilities to be canvassed at examination.

Continuing to recognize the traditional division into the congenital and the acquired varieties, recent publications emphasize the congenital factor, whereas in earlier days the acquired form, principally that resulting from violent crushing injury, was stressed. Modern case reports appear to indicate that whereas an increase of intra-abdominal pressure, which need not be extreme, is often doubtless the immediate cause of hernia, congenital gaping of the hiatus oesophageus or other anatomic foramina, or developmental weakness in other portions of the diaphragm, is usually a significant predisposing element. In short, a closer similarity between diaphragmatic hernia and inguinal hernia is becoming apparent. Thus the opinion of Jenkinson [1] that the hiatus hernia, which is often slight, is the most frequently encountered type and is relatively common, finds confirmation in the observations of Åkerlund,[2] Ude and Rigler,[3] Morrison [4] and Healy.[5] An interesting variety of this type is that in which the esophagus is congenitally shortened. However, when the entire stomach lies above a normally developed diaphragm, LeWald,[6] following Bailey, prefers the designation "thoracic stomach" and classifies it apart from the hernias. Besides greatly swelling the records of hiatus hernias, case reports over the last five years deal with traumatic hernias through breaches in various parts of the diaphragm, parasternal and other hernias, congenital or acquired, all differing in details but fundamentally alike in their diagnostic problems. The aggregate of new reports tends to confirm the accepted fact that the stomach is most frequently implicated in the hernia and is followed by the colon, small bowel, omentum, spleen, pancreas and liver, singly or in varying combinations.

To the clinical side, little new has been added. Except in the typical traumatic cases with a history of wounding by knife or by gunshot, or of crushing injury or violent forward flexion of the body, a clinical diagnosis or even surmise of diaphragmatic hernia is scarcely to be expected. The symptoms may be chiefly gastric or thoracic, or both, and vary widely in character and intensity; although physical signs may be pronounced, they are most often odd and perplexing. With the facile means of examination afforded by the roentgen ray, there is little incentive for assiduous clinical study of the condition. Of 690 cases reviewed by Giffin [7] up to 1912, only fifteen had been diagnosed clinically. Of all cases now on record, the vast majority were revealed by the roentgen ray. Obviously, then, the roentgenologist has a virtually clear field and a proportionate responsibility for this diagnosis. Since so many of the 110 cases seen at the Mayo Clinic have previously been reported from the clinical, surgical or roentgenologic standpoint by Harrington,[8] Beckman,[9] Carman and Fineman,[10] Balfour,[11] and Fineman and Conner,[12] a statistical analysis of the entire series would be repetitive and tedious. It will perhaps be more profitable to review the subject from the roentgenologic angle in the light of a broadened general experience and of our own observations.

As in many other diseases, the chief obstacle to the diagnosis of diaphragmatic hernia is neglect to look for it; and, since all examinations are ordinarily made at the direction of the clinician, he must share blame with the roentgenologist for many failures of diagnosis. We are here concerned, however, not with the particular signs or symptoms, if any, which should direct the clinician's attention to the possible presence of a hernia, but with the roentgenologist's opportunities and duties. Such opportunities he may find in each of three separate examinations which he is constantly making; namely, those of the thorax, stomach and colon.

Theoretically the diagnosis should offer no great difficulty, since it depends essentially on the demonstration of abdominal organs above the diaphragm and in the thorax, where roentgenologic changes are readily apparent. Nevertheless, the differential diagnosis is often hard, even when the hernia and its manifestations are pronounced, and many hernias, especially those which are small, are reduced by the standing position

commonly employed for the inspection of the stomach and thorax. Consequently, the examiner is often obliged not only to consider all details with extraordinary care, but also to resort to special technics.

Patients with diaphragmatic hernia are frequently sent first for roentgenography of the thorax, because this is almost a standard feature of routine examinations and because it may be called for by the thoracic symptoms. Unless the hernia is extremely small or is reduced spontaneously at the moment, thoracic changes will be evident in the roentgenogram. Obviously the roentgenographic manifestations will vary with the site and extent of the hernia, the organs intruded into the thorax, and, if the stomach and bowel are implicated, their contents, whether gas, fluids or solids. In classic instances when the hernia is gross and includes the stomach or colon the roentgenogram alone may be diagnostic if the gas-bubble of the stomach or the transradiant haustra of the colon can be identified and their supradiaphragmatic situation is evident. Not always, however, is even a marked herniation of the stomach recognizable, for the dome of the cardia may reach from the midline to the thoracic wall and be confounded with an elevated diaphragm. Further, as Carman and Fineman have pointed out, a partial hernia of the stomach filled with gas and fluid may closely imitate hydropneumothorax or an echinococcus cyst, loops of gas-filled bowel may resemble bronchiectatic cavities, and other hernias may be mistaken for subdiaphragmatic abscess, multiple abscesses of the lung, or pleuritis with or without effusion. It is difficult to realize the striking similarity of these and other pleural, pulmonary or mediastinal lesions to hernia unless the films are placed side by side. The conclusion is inescapable that in studying roentgenograms of the thorax, no matter what the purpose of the examination or the tentative clinical opinion, diaphragmatic hernia must be kept constantly in mind, and in all doubtful cases examination of the alimentary tract with opaque mediums is to be advised.

It is to be assumed that in all examinations of the stomach the esophagus also will be inspected, since peculiarities in the passage of the barium stream through the esophagus often betray the presence of a hernia. The behavior of the stream varies with the type of hernia. In the variety with a short esophagus the shortening is evident and the barium enters without hindrance into the stomach, the rugae of which distinguish it from esophageal dilatation or diverticulum. In persisting para-esophageal hernia the barium descends through a more or less tortuous lower segment of the esophagus, in which it is inclined to tarry, and then rises to enter the herniated portion of the stomach. Herniation of the stomach through breaches elsewhere than at the hiatus is almost invariably attended with a notable delay of the barium in the lower part of the esophagus, the epicardial portion of which is tensed and often sharply angulated at the hiatus. Logically, then, any deviation in the terminal course of the esophagus or retarded entrance of the barium into the stomach, although often due to other causes, should at least suggest the thought of hernia.

Distortion of the stomach in hernia of any type is variable in degree and configuration. Rarely, as in congenital absence of the left diaphragmatic arch or in gross traumatic hernia, little distortion occurs. Most often, however, the stomach is only partially herniated, and hour-glass deformity results rather constantly. Since the fundamental distinguishing mark of hernia is the supradiaphragmatic situation of abdominal organs it is necessary, although sometimes difficult, to trace the outline of the arches. Often the arch is irregular, or sinuous, or angulated at the point of rupture, or the margins of the breach may form a visible collar. Respiratory movements of the arch may be normal, diminished, absent or reversed, depending on the size of the hernia and the extent of fixation by adhesions. Completing the picture are displacement of the heart, if the hernia is large, and shading of the lung in proportion to the amount of compression.

To elicit these manifestations and study them satisfactorily, the ordinary technic is often inadequate and must be supplemented by special methods. Contours of the arches should be traced at all practicable angles, and many observers dwell on the advantages of the lateral view. By causing the patient while in the standing position to inspire deeply, or bend forward, or by strong manual pressure over the abdomen, a spontaneously reduced hernia can sometimes be made to reappear. Often by these maneuvers a small hernia of the stomach, especially one at the hiatus, is not depicted by the barium but by air forced out from the gas-bubble.

From the earliest employment of the roentgen ray for the exhibition of diaphragmatic hernia the recumbent position, prone, supine, lateral or Trendelenburg, has been recommended to demonstrate hernias which might spontaneously have been reduced in the erect posture. At the Mayo Clinic we have often had recourse to the prone position, and this posture together with manual pressure on the abdomen has revealed hernias which had not been demonstrable otherwise. Until of late, however, most examiners have employed recumbent positions only in cases in which there was a strong suspicion that a hernia existed despite negative observations in the erect posture. Jenkinson, Åkerlund and others have rendered outstanding service in this field, not only by proving the relative frequency of small, reducible, hiatus hernias, but also by reemphasizing the necessity of employing recumbent positions to discover them. By way of corroboration, it may be mentioned that in a selected group of thirty-two patients sent recently for examination of the stomach, the results of which were negative in the standing posture, two were found to have a definite hernia through the hiatus when examined in the prone position. In this group a special search for hernia was stimulated by the fact that several of the patients had symptoms compatible with hernia, in several the lower end of the esophagus deviated to the right in a manner suggestive of displacement by hernia, and all the patients were of the broad habitus. On the other hand, in a consecutive series of 300 patients, only one patient was similarly discovered to have a hernia through the hiatus.

It would seem that no roentgenologic examination of the stomach is decisive unless both the erect and the recumbent posture are employed and a careful search is made for evidence of diaphragmatic hernia. On the other hand, excessive zeal in this direction might lead to substantial error, for exact knowledge is lacking as to the clinical significance of certain small hiatus hernias, some of which might be regarded as potential rather than actual. It is probable that the size of the esophageal hiatus varies considerably among normal and comparable persons, and that the tone of the diaphragmatic muscle fibers which enclose it is a modifying factor. In a small series of patients operated on at the Mayo Clinic for conditions other than hernia, the surgeon explored the hiatus and found that in several it would accommodate three fingers, yet at subsequent roentgenologic examination no evidence of hernia could be elicited. Cardio-esophageal relaxation, characterized by dilatation of the epicardia and ready reflux of barium into the esophagus, as reported by Robins and Jankelson[13] in more than 100 cases and which we have observed repeatedly, might be confounded with hernia by an overkeen examiner.

Diaphragmatic hernia cannot absolutely be excluded without examination of the colon with the barium enema, and this is frequently necessary to confirm or exclude participation of the colon in known cases of hernia. Rarely, the small bowel alone is implicated, and serial observations of the opaque meal may be advantageous or necessary in establishing the diagnosis.

Hernias through the right arch of the diaphragm are in the minority, the ratio to left side hernias being variously estimated. Usually a portion of the right lobe of the liver protrudes through the breach, and the prominence is conspicuous against the lung field, but it may be mistaken for an hepatic tumor. Occasionally the colon alone or in conjunction with other organs is extruded through the right leaf. Right hernias of the colon may require distinction from the rare instances in which the hepatic ligaments are lax and the transverse colon overlies the liver. In this connection also it is noteworthy that hernias through the esophageal hiatus may intrude into either the right or the left half of the thorax. On the whole, whatever their portal of entry, hernias into the right thoracic space are likely to be more perplexing than those on the left.

A closer approach to accuracy in the differential diagnosis of diaphragmatic hernia is no doubt accountable in part for the increasing number of case reports. It is probable that in the past small hernias of the stomach, through the hiatus, have frequently been mistaken for esophageal diverticula, although the latter should be distinguishable by the absence of rugae. Eventration is perhaps the most deceptive simulant of hernia. Reversed, or paradoxic, respiratory movement of the affected arch was for a time regarded as a distinguishing sign, but recent observers agree that respiratory movement may be normal, diminished, absent or reversed in either hernia or eventration. A more practical point of distinction, advanced by Morison,[14] is that in eventration the upper level of the barium in the stomach always coincides with the esophageal opening when the patient is erect, whereas in hernia the upper level of the gastric content is likely to be above the plane of the esophageal aperture. Further, in elevation the line of the arch, which can be seen to advantage in the lateral view, is regular and unbroken, and no shadows of abdominal viscera lie above it. Hour-glass deformity of the stomach caused by hernia resembles that produced by gastric ulcer or cancer, and an ulcer with a visible niche may occur at the hernial constriction, but the distinctive feature of hernia is the supradiaphragmatic situation of the upper loculus.

SUMMARY

The present status of the roentgenologic diagnosis of diaphragmatic hernia may be summed up as follows:

1. The incidence of the condition is higher than it has been assumed, and hernias at the esophageal hiatus are relatively common.
2. Hernia should always be considered in examinations of the thorax and especially when anomalous shadows are seen in the lower thoracic fields.
3. In examining the stomach, hernia cannot be excluded without the employment of recumbent postures and manual pressure over the abdomen.
4. It cannot be excluded without examination of the large bowel, for the colon alone may be implicated.
5. Its distinction from other lesions depends on the demonstration and identification of abdominal viscera above the diaphragm; neither normal nor altered respiratory movements of the diaphragm are reliable as differential criteria.
6. The clinical significance of small, impermanent hernias at the hiatus which are demonstrable only under more or less artificial conditions has not been fully determined.

ABSTRACT OF DISCUSSION

Dr. E. L. Jenkinson, Chicago: Lesions of the diaphragm are interesting. At times they are difficult to identify. In a great many instances probably these small hernias are of no importance, because they cause no symptoms, and in these instances the patients are not treated. Five years ago I saw a small hernia of the diaphragm through the esophageal opening. The patient would not subject herself to surgery and she would not take medical treatment. She kept eating large meals and would go to bed immediately after she had eaten. Five years later, the sac was large, about the size of an orange. If these patients are not operated on or if they do not follow the medical regimen and are not careful in the amount of food they eat or if they take large amounts of fluid and retire immediately, I think that the sacs get larger and, later, cause symptoms. I do not think that the classification of these lesions is of importance. Whether they are eviscerations due to injury or whether they are congenital, they generally cause the same symptoms. I think that most congenital hernias have a sac, whereas eviscerations or traumatic hernias do not have a sac; they have, as a rule, a covering of the hollow viscus over them. I don't believe that paradoxic movements of the diaphragm occur in the smaller hernias. They do occur occasionally in large hernias through the central tendon. Occasionally, one may get a paradoxic movement at one examination, and at a second examination the movements may be normal. I don't believe that a short esophagus has been encountered very often, even in large hernias. The esophagus, as a rule, is of normal length. I think that some of the instances of short esophagus reported are due to the fact that these hernias which occur through the esophageal opening have a high diaphragm; the stomach rotates and the sac goes up alongside the esophagus. As a rule, with the large hernias, the esophagus can be traced around the sac. Hernias are important regarding diagnosis with especial reference to hydropneumothorax. Recently I saw a patient who had had a rib resection. The child's stomach was up in the chest. It is important that these patients be examined carefully, and especially is this true in children. It has been my experience that large hernias, when most of the stomach and a large part of the small and large bowel are in the chest, usually occur in children. Whereas, in patients who develop them or have symptoms in adult life, the hernias are usually small.

Dr. L. T. Le Wald, New York: One point that was mentioned and should never be lost sight of is that in any peculiar appearance about the diaphragmatic region one should never make a positive diagnosis without roentgen examination with opaque material in the digestive tract. A case occurred in my service at one of the hospitals in which an assistant made a diagnosis of thoracic tumor on the right side. There was a projecting shadow above the diaphragm but no barium study was made. The next thing I knew was that an exploration had been done by a thoracic surgeon, who found an omental hernia protruding through the diaphragm. There had been no gas or anything to give a clue to the fact that the shadow in the chest was due to a hernia. It had quite a smooth border and it had been diagnosed as an intrathoracic tumor or cyst and I have no doubt that if one had given barium one would have seen some displacement of the colon or stomach enough to give a clue to the fact that it might have been an omental hernia. The patient died of pneumonia following the operation. Thoracic stomach ought to be classified under the general heading of hernia, but with this distinction, that this type should never be operated on with the idea that the stomach can be brought down into the abdominal cavity, because it cannot be done on account of the short esophagus. Unless one is going to do some peculiar type of plastic operation to elongate the esophagus, no operation should be attempted. Some cases of eventration deserve operative intervention. In two patients, eventration had come on after removal or resection of the phrenic nerve to collapse the left side of the chest for tuberculosis. The other type of case that I want to stress is the complete absence of one half of the diaphragm. If one reads the reports of some of these cases, one will see that it is impossible at the present time to get sufficient tissue to repair a defect as large as this. If one could be sure that one had a defect as large as this, one probably would feel like discouraging any operative attempt to repair it, but might operate for some complication. The contents in my case were the stomach and the colon together with the cecum and a good deal of the small intestine. Dr. Sante just told me about a case in which an ulcer perforated into a herniated stomach. I heard of a case of diaphragmatic hernia in which an appendix ruptured into the chest cavity.

[14] Morison, J. M. W.: Elevation of the Diaphragm: Unilateral Phrenic Paralysis, Arch. Radiol. & Electroth. 27: 353-364 (May), 28: 72-83 (Aug.), 111-123 (Sept.) 1923.

Dr. William A. Evans, Detroit: A greater incidence of diaphragmatic hernia may now be expected, owing to the increasing popularity of phrenic nerve operations for tuberculosis and other thoracic conditions. The proponents of this surgical procedure deny that this will happen, but in statistics recently compiled by a German surgeon, one case of true diaphragmatic hernia occurred in a group of thirty-five patients who had been operated on. If this ratio prevails in Detroit, where one surgeon alone has paralyzed the diaphragm in more than 800 patients, it is obvious that the frequency of this condition will be greatly increased.

Dr. B. R. Kirklin, Rochester, Minn.: We did not discuss the thoracic stomach because we felt that it should not be included in a paper on diaphragmatic hernia. So far as I know, no attempt has been made at the Mayo Clinic to repair the diaphragm in cases of eventration. One thing that I wish to stress is the extreme difficulty of demonstrating some of these hernias. As an example, I recall the case of a truck driver who was injured in an automobile wreck. This man was examined in Minneapolis by a competent roentgenologist who found about two thirds of the stomach and part of the colon extruded through a rent in the diaphragm and accordingly returned a diagnosis of hernia. The patient came to the Mayo Clinic and was sent to the roentgenologic section for examination. Although aware of the diagnosis that had been made, and although films of the chest indicated that the diaphragm had suffered injury, neither Dr. Moore nor myself was ever able at repeated examinations to exhibit the hernia with the barium meal or to demonstrate any abdominal viscera above the diaphragm. The patient was operated on and the hernia successfully reduced.

Habit Clinics.—Habit clinics have some points in common with the "rest cures" to which wealthy women go. They are places where children go to recover from the abnormal home conditions. The effort of those in charge of the clinic is directed toward changing the beginning pathological habits into which the children have fallen. After a period of treatment, they are returned to their homes, where the same conditions again renew the habits that sent them to the clinic. While children are attending these "mental sanitariums" their parents should also undergo a course of habit treatment. In some way the vicious circle ought to be broken. The circle, which begins with the lack of knowledge of the neurasthenic mother, continues in the disturbed mental poise of the child and follows the same old course in the home, never deviating from the vicious path of parental irritation, nervous response and repeated irritability alternating with sentimental indulgence of the child.—Swift, E. J.: The Psychology of Childhood, New York, D. Appleton & Co., 1930.

THE ORIGIN OF POLYPI OF THE LARGE BOWEL

WITH ESPECIAL REFERENCE TO ADENOMA: PRELIMINARY REPORT *

W. A. FANSLER, M.D.
Assistant Professor of Surgery, University of Minnesota Medical School;
Associate Surgeon, Minneapolis General Hospital
MINNEAPOLIS

Polypi may occur in almost any portion of the intestinal tract, but approximately 75 per cent of these occur in the large bowel. Broadly speaking, any pedunculated tumor extending into the lumen of the bowel may be termed a polypus. This broad usage of the term has brought about considerable confusion. Of the more unusual type may be mentioned fibromas, lipomas and myxomas arising from the areolar tissue of the bowel wall; myoma arising from the muscular coats, and hemangioma arising from the blood vessels. Certain other tumors arise outside the bowel wall but protrude into the lumen of the intestine in a polypoid fashion. Among these may be mentioned postsacral dermoid cysts and meningocele. Occasionally there is a polypoid growth due to parasites such as *Oxyuris vermicularis* or *Schistosoma hematobium.* This group does not compose more than 5 per cent of all polypoid tumors of the large bowel. Their origin is obvious and they will not be discussed further.

The second group has to deal with the epithelium of the large bowel. Of this group there are two divisions. The first, or inflammatory, type is seen in cases of ulceration of the bowel due to ulcerative colitis, amebic dysentery, syphilis, tuberculosis and other inflammatory conditions. Polypoid flaps or tags extend into the bowel. The mucosa is thickened, edematous and inflamed, but with the disappearance of the ulceration these polypoid flaps also disappear. These are in no sense true tumors, as there is no growth of the epithelial tissue.

The second type is the adenoma or adenomatous polypus, and it is with this group that this paper is chiefly concerned. These tumors are true adenomas, whose epithelial structure is derived from the cells of the intestinal mucosa. They protrude into the bowel lumen and eventually become polypoid through the traction of their own weight, the pulling of the fecal current and the peristaltic action of the bowel itself. Erdmann and Morris [1] have given a classification which is widely quoted. They divide the tumors into the adolescent (congenital disseminated) type, which they have seen in the first two decades of life, and the adult or acquired type, which appears in later life. I have never been able to match this classification with my own experience. As a matter of fact, children usually have a single adenomatous polypus. I have never seen a child under 10 years of age with more than two adenomatous polypi, and I have never seen a case in which the bowel was studded with numerous adenomatous polypi in a patient who was under 18 years of age. In fact, I have come to regard the type of case in which numerous adenomas are present as a condition occurring in adult life, in what may be termed the "precancer years," that is, the late twenties or early thirties or later. No doubt there are exceptions, but as a rule I believe that single adenomas occur in the earlier years of life and multiple adenomas in the later years.

[1] Erdmann, J. F., and Morris, J. H.: Polyposis of the Colon, Surg. Gynec. Obst. **40:** 469 (April) 1925.

A typical adenomatous polypus may be described as consisting of a stalk or pedicle, which may be short and thick or long and thin. This depends on the duration of growth, blood supply and certain extraneous factors, as bowel peristalsis and fecal current. The stalk is covered with one layer of mucosa such as lines the intestine. If the adenoma becomes cancerous the cancer cells often invade the pedicle. The central portion of the stalk is made up of connective tissue continuous with that of the bowel wall. It also contains blood vessels and nerves. On reaching the body of the adenoma the stalk appears somewhat compressed and then its component structures branch out to form the framework of the tumor. The tumor itself is usually round or oval and of a darker red than the normal mucosa. It is lobulated after the manner of a cauliflower. The surface appears velvety and bleeds easily to touch. The epithelial covering shows cells with more mucus than normal, and often more than one layer in thickness.

This is a typical adenomatous polypus, but it is not always the picture seen through the proctoscope. Trauma, inadequate blood supply and infection frequently produce superficial ulceration. In time, this results in fibrosis with the end-results that the tumor appears as the smooth, hard whitish type of polypus in which little adenomatous structure is left.

How do these tumors originate? What factors influence their growth? Why do some degenerate into carcinoma and some not?

As to why these tumors form, let us first consider the question of special susceptibility or tendency of an individual to form adenomas. I think that it is fairly obvious that some such tendency does exist. This may be simply a question of a certain type of mucous membrane or some deeper inherent characteristic, influencing tumor growth, which the present knowledge of body chemistry, pathology and bacteriology has not been able to determine. At least it is known that in some cases a definite family tendency can be shown. Jüngling[2] traced this characteristic through three generations of several different families. Of course, usually a single individual in a family is affected. Owing to the fact that propagation of the human race is done in such a haphazard manner and ancestral diseases are so little known to the average individual, this apparent isolated appearance of the multiple adenomas proves little if anything, as far as inherited tendency is concerned. This single case may appear in an apparently nonadenomatous family, just as an occasional white mouse may appear in what is apparently a pure strain of gray mice. If the strain is checked back, usually a white mouse can be found among the ancestors.

Aside from the question of predisposition, two theories are advanced as to what actually occurs in the formation of the tumors. The first is that they result from areas of chronic mucosal irritation. Adenomas are often found in chronically inflamed areas. Certain tumors tend to develop in chronically irritated areas.

The second theory assumes the primary change to occur in the epithelial cells and the inflammatory change to be secondary. The fact that the mucosa adjoining the adenoma is frequently normal would point to this. Saint[3] believes that the tumor begins as a hyperplasia and hypertrophy of the epithelial cells, with submucous thickening, and the pedicle is formed as the tumor becomes progressively larger and traction is made by the fecal stream and peristalsis of the intestine.

I do not believe that the primary change is in the epithelium. It is my opinion that the primary lesion lies underneath the intestinal mocosa. The tumor begins as an enlargement of a small submucous nodule of lymphoid tissue and the epithelium over it is normal. What is the exciting cause for this primary enlargement I cannot say. It may be infection (plus predisposition), but if so there is no definite ulceration of the bowel wall. The sequence of events in the formation of these adenomas was noted during examination of cases in which single and multiple adenomas were present. In one spot would be a typically pedunculated adenomatous polypus, in another simply a little bulge of the mucosa as though there were a foreign body lying under it. A small hard nodule could be felt underneath, and the mucosa over this bulge appeared normal or slightly reddened. Many areas of mucosa were perfectly flat and normal in appearance. If, however, these normal areas were palpated with the finger tip, in some cases a small hard nodule could be felt underneath the mucosa. These nodules were about the size of a BB shot or even smaller. Excision of these nodules of various sizes revealed a uniform picture. Over the small nodules the mucosa was normal. As the nodule enlarged and pressed against the mucosa, pushing it into the lumen of the bowel, changes began to occur. The epithelium appeared irritated and in later stages began to dip down in true adenomatous fashion, the tumor became button-like and finally pedunculated.

Once formed, what influences the growth and end-results of the tumor? This probably depends on several factors. It is known, of course, that each tumor possesses its own blood supply. That is, that blood vessel formation occurs along with the development or in fact precedes the actual growth of the tumor. The primary vessels arise from the vessels of the bowel wall at the point of origin of the tumor. It is quite conceivable, then, that if the point of origin of the tumor happens to be in a rather avascular area of the bowel wall no very large blood supply can be developed. The growth of the tumor will be restricted and it will likely remain small and eventually retrogress into a polypus of the hard fibrous type. Of course superficial infection, torsion and attenuation of the pedicle also plays a part in these changes.

On the other hand, if the point of formation of the tumor is near a large blood vessel, the growth will be rapid and the tumor large. Theoretically, at least, the tumor could continue to grow indefinitely, though in reality the same factors already mentioned do produce fibrosis in some of these. There is little doubt, though, that it is this type with a liberal blood supply which, left undisturbed, eventually undergo carcinomatous change. It should also be mentioned that the nerve supply of a given tumor might influence the rate and extent of growth. Oertel[4] and others have shown tumors to have a definite nerve supply, but what influence this may have on growth has not been determined.

While the exciting cause or causes of the formation of adenomatous polypi of the large bowel are not definitely known, I am convinced that the earliest demonstrable pathologic change is not found in the cells of the mucosa lining the bowel, but as a nodule of lymphoid cells in the submucosal tissue.

FACTORS INFLUENCING THE TREATMENT OF RECTAL CANCER *

GEORGE E. BINKLEY, M.B. (Tor.)
Associate Surgeon, Memorial Hospital
NEW YORK

The treatment of rectal cancer is a perplexing but interesting problem, on account of the numerous variable factors associated with this disease at the time a definite diagnosis is determined. Results will depend largely on the extent of the disease, the selection of cases and the type of treatment employed.

The manner in which cancer begins within the rectum is largely unknown. The consensus, however, is that it arises as a more or less circumscribed area in the rectal mucosa, where the glands undergo hyperplasia and hypertrophy. Dukes suggests that the origin of rectal cancer is closely associated with the simple adenomatous tumors. Regardless of the lack of knowledge of the earlier stages, it is known that the alveoli of the primary focus soon break through the tunica propria into the submucosa, where they gradually invade the lymphatics and muscular coats. The cell proliferation produces tumors which vary in the rates of enlargement, of infiltration and of dissemination.

Early recognition of rectal cancer, while the tumor is small and the disease is localized, offers many advantages to successful treatment. Unfortunately, a high percentage of these cancers are not recognized while in this favorable condition. Late diagnosis is frequently due to the failure of the patient or the clinician to interpret the symptoms properly, prior to the time the tumor has reached the sloughing stage. The percentage of early diagnosis of rectal cancer will be greatly increased when a rectal examination constitutes a part of the routine physical examination of all patients who present indefinite gastro-intestinal symptoms.

The chief problem to be solved after the true nature of the disease has been determined is that of providing the patient with the most appropriate treatment. The two methods of treatment that have proved of greatest value in this disease are radiation therapy and surgery. There is not any routine dosage of radiation therapy nor any routine surgical procedure suitable for all cases. In a miscellaneous group, the best results are obtained, in properly selected cases, by the unbiased and combined use of these two methods, and by varying the dosage and technic in accordance with the clinical and pathologic features of the given case.

The two forms of radiation therapy that have proved of greatest value in these deep-seated tumors are external applications of radium and roentgen rays, and interstitial applications of radon filtered by 3 mm. of gold. The surgical procedures that offer the greatest possibilities are the abdominoperineal and the perineal types of operations, while a colostomy affords a certain degree of palliation to the inoperable group.

Although the treatment of each case is a separate problem, a working classification is essential for descriptive purposes. Prior to the time that radiation therapy was found capable of producing clinical cures in this disease, cases were classified from a purely surgical point of view into operable and inoperable groups. The operable group consisted of those cases in which a radical operation offered the greatest possibilities of a clinical cure or the highest degree of palliation, while the inoperable group comprised those cases in which there was extensive disease or in which the patients were in poor physical condition and were therefore unsuited for such operations. Now that additional facilities are available for treatment, it appears more appropriate to classify cases of rectal cancer as favorable and unfavorable. As the favorable patients are those presenting strong possibilities of being rendered free from disease by surgery, radiation therapy or the combined use of radium and surgery, a number of inoperable cases will fall within the limits of the favorable group. Unfavorable cases are those suited only for palliative measures.

The importance of the latter classification may not at first sight be fully appreciated. By selecting cases in accordance with the character of the clinical and pathologic features rather than the operability, a higher percentage of clinical cures is likely to be brought about, and patients with unfavorable features are not subjected to dangers and discomforts of radical methods of treatment. Irradiation usually offers the inoperable patient much greater palliation without the possibility of an immediate fatality, than that provided by incomplete removals. Factors that suggest this classification and offer a rational basis for the most appropriate treatment are: (1) the physical condition of the patient; (2) the size of the tumor, together with the extent of infiltration and dissemination of the malignant cells; (3) the location and accessibility of the cancer; (4) the degree of malignancy of the neoplasm; (5) the degree of radiosensitivity of the cancer cells.

The physical condition of the patient should receive primary consideration, as the severity of treatment should not exceed his endurance. Only those patients who are able to withstand treatment adequate for the eradication of the disease are considered as favorable. Moreover, the degree of palliation in the unfavorable group frequently depends on the physical condition. The strain of radiation therapy is usually much less than that of radical surgery. A number of patients who because of their physical condition are unable to withstand a radical operation may be rendered clinically free from cancer by radiation therapy. Special attention should be given the physical condition when radical surgery is required. The selection of the type of operation is important, as certain surgical procedures are accompanied by a higher immediate mortality than others. The ultimate results of radical surgical removals will depend largely on the selection of cases, the type of operation, and the skill of the operator.

The ability of the patient to withstand treatment is estimated from the physical examination and laboratory observations. Old age, chronic constitutional diseases and obesity often limit treatment that otherwise might appear appropriate for the local malignant condition. The strain of an operative procedure may often be lessened by careful preparation of the patient, by the use of spinal anesthesia, and by preoperative transfusions of blood.

The estimation of the extent of disease is of vital importance in outlining treatment. Rectal cancer increases by direct extension and by the lymphatic and blood streams. Unless the disease is localized to the degree that all the malignant cells can be devitalized or removed, a clinical cure is impossible. The extent of the dissemination may be predicted from the history, physical examination, and the size, shape and degree of malignancy of the cancer. However, a more definite

---

* Read before the Section on Gastro-Enterology and Proctology at the Eighty-First Annual Session of the American Medical Association, Detroit, June 25, 1930.

estimation of the spread of disease is possible by a careful exploration of the abdominal cavity, and by rœntgenograms of the pelvis and the lumbar vertebrae.

The local extent of the primary focus may be fairly accurately estimated by digital and proctoscopic examinations. The degree of infiltration and fixation are of value in determining the prognosis, as they are a fair criterion of the extent of invasion beyond the rectal wall. The importance of the infiltration will depend on what tissues are invaded and on the degree of malignancy of the cancer. Certain types of highly malignant tumors which have a tendency to infiltrate early and widely are seldom favorable, because the disease has usually extended much farther than the induration would indicate. Invasion of the bladder and the vagina usually contraindicates radical surgical intervention. Partial fixation may be due to inflammation or to the extension of the disease. Differentiation is often made possible by administering a moderate dose of external irradiation. The size of the mass, provided the disease remains localized, has but little bearing on treatment, except when interstitial irradiation is employed, when the dosage is always varied in accordance with the size of the mass.

The extent of disease limits the degree of palliation in the unfavorable group. The object of treatment in this type of case is to produce the highest favorable degree of restraint of growth and thereby to decrease the symptoms and improve the general condition. The dosage required to bring about uniform restraint varies with the size of the mass, but reactions may be lessened by using fractional doses and extending treatment over a longer period of time. The amount of infiltration and the involvement of nerve filaments will largely govern the degree of discomfort. Cancers that have invaded the pelvic tissues to the extent of producing constant pain are unsuitable for intensive treatment. Overdosage of interstitial irradiation in the advanced stages is detrimental rather than beneficial.

The anatomic location and accessibility of cancer within the rectum may greatly influence the selection of treatment. Radiation therapy is the method of choice for patients who can be rendered clinically free from disease by this comparatively simple method of procedure. However, favorable tumors selected for this form of treatment, unless highly radiosensitive, will require implantations of radon. Adequate interstitial irradiation can be carried out only when the tumor is sufficiently accessible to allow a proper placing of the emanation seeds. While tumors at any location between the rectosigmoidal juncture and the anal canal may be accessible, those of the middle and lower rectum frequently permit more accurate implantations. In the latter positions the needles may be inserted by way of the anal canal, the perineum or, in women, by the posterior vaginal wall. When partial stenosis of the lumen at the upper locations prevents the proper distribution, this difficulty may be overcome by the construction of a preliminary colostomy. In the construction of such an artificial anus, the section of sigmoid between the opening and the tumor is left sufficiently short to allow the passage of a proctoscope through the opening downward to the upper area of the cancer. Accessibility also aids the efficiency of palliative radiation therapy.

The most thorough surgical dissection for cancer at any location within the rectum is by the abdominoperineal type of operation, completed in one or two stages. However, because of the inability of many patients to withstand such a radical operation, this form of procedure is not always the method of choice. The perineal type of operation, when preceded by a colostomy, is accompanied by a much lower mortality and is capable of producing satisfactory results in properly selected cases. This procedure is most suitable for tumors situated below the reflection of the pelvic peritoneum. Therefore, the location of the cancer may be an important factor in determining the most appropriate type of operation.

The location and accessibility of cancer may afford advantages not only for either radiation therapy or surgery but also for the combined use of the two methods. While preoperative irradiation is valuable in a fair percentage of operable cases in providing additional assurance against incomplete removals it is of greatest value in fairly well advanced rectal cancers situated below the reflection of the pelvic peritoneum. Large tumors that have infiltrated beyond the reach of purely surgical dissection often lend themselves exceedingly well to the combined use of radium and surgery. In this type of case, radium is employed for devitalization of the cancer cells, and surgical removal for the prevention of the severe reaction that may be expected to follow large doses of radium. The method has its widest applications in large pelves. The vagina offers additional facilities for the implantation of radon into the tumor and limits the anterior spread of disease. The difficulties of surgical removal are not increased by preoperative therapy unless an interval longer than two weeks is allowed to elapse between procedures.

There is a wide variation in the degree of malignancy of rectal cancer, a fact clearly demonstrated by any group of untreated patients, in whom the duration of disease will vary from one to four years. The difference in the pernicious qualities of cancer had long been recognized, but it remained for Broders to emphasize this important factor and offer a working classification. Rectal cancers of low grade are usually much more amenable to treatment than those of a higher grade of malignancy. Through recognition of the type of malignancy before treatment is undertaken, many patients with incurable highly malignant cancers will be saved the unnecessary annoyance of radical procedures, while on the other hand patients with tumors of the lowest degree of malignancy will be rendered free from disease or provided with the highest degree of palliation.

In determining operability, the grade of malignancy is deserving of equal consideration to that afforded the extent of disease. A moderate-sized low grade rectal cancer in which the disease appears to be more or less localized may be completely eradicated by surgical dissection, while a similar surgical procedure, in the case of a tumor of the highest grade of malignancy but similar in size and fixation, is more likely to be detrimental than beneficial. Moreover, the grade of malignancy suggests a solution of the problem in determining the most appropriate type of operation. Operable tumors of low grade malignancy in the middle and lower rectum can usually be satisfactorly removed by the perineal route when the operation is preceded by a colostomy, while operable tumors of the rectosigmoidal juncture and those of a high grade of malignancy, wherever located, usually require the more extensive abdominoperineal resection.

The malignant qualities also influence the technic and dosage of radiation therapy. Highly malignant tumors are cellular and usually radiosensitive and require a comparatively small dosage. Overdosage in this type of cancer tends to produce necrosis and sloughing. In certain instances the employment of interstitial irradiation is contraindicated. Tumors of a low grade of malignancy lend themselves well to the latter form of treatment, although they require for devitalization a comparatively large dosage of gold seeds.

The malignant qualities of rectal cancer are manifest in the rate of enlargement of the primary mass, the rate of infiltration into the surrounding tissues, and the rate of dissemination of the cancer cells to distant regions. These factors vary in different tumors, as certain types will disseminate very early in the course of the disease, while others will remain localized for comparatively long periods. A fairly accurate estimation of the degree of malignancy may be obtained from the history and physical examination, and from the clinical and histologic examination of the mass.

Cancers occurring in patients below the age of 30 are usually highly malignant. Above this age there are many exceptions to the rule that the younger the patient *the more malignant the cancer.* The *duration and* severity of the symptoms in comparison to the size and fixation of the primary mass is of importance in estimating this factor. A long history of mild subjective and objective symptoms associated with a comparatively small tumor without deep infiltration suggests low malignancy, while a sudden onset of severe symptoms of only a few months' duration accompanied by a comparatively extensive mass indicates a more highly active process. The onset and rate of progression of anemia, weakness, loss of strength and other constitutional symptoms are usually in proportion to the degree of malignancy.

Tumors of the various grades present different clinical appearances. The rapidly growing, early infiltrating cancers tend to encircle the rectum, pushing the mucosa inward. They are most frequently encountered about the middle of the rectum in young women. The mass grows rapidly and usually has attained a large size before ulceration takes place. There is much less induration than in other types. The most pernicious quality of this type is the early and wide infiltration, as dissemination takes place comparatively late in the course of the disease.

The clinical appearance of another common highly malignant type is quite different. This variety enlarges slowly, but infiltration and ulceration occur early in the course of the disease. Usually the picture presented is that of a comparatively small tumor with a crater in the center and elevated degenerated edges. Fixation is at the base of the crater. Bleeding is easily produced by mild trauma, and considerable infection is noticed. The most common location for this variety is in the lower rectum. Histologic study of the foregoing types suggests either grade 3 or grade 4.

The *most common* type of *rectal cancer* is of *medium* grade malignancy, usually classified histologically as grade 2. In this type there is more uniformity of the rate of enlargement, of infiltration and of dissemination than in other varieties. In other words, the size of this type of tumor, its degree of infiltration and its extent of dissemination are in about the same ratio. These tumors lie in different locations within the rectum and are most frequently encountered in patients between 40 and 65 years of age. There are several distinct clinical types of tumors of medium malignancy which may be readily recognized by their own typical appearance.

The commonest variety of the least malignant rectal cancers is the stenosing scirrhous tumor, which occurs most frequently in elderly patients. They encircle the bowel and cause a constriction of the lumen by narrowing or squeezing in its circumference. The bulk of the cancer remains within the constricted rectal wall and does not extend outward into the lumen. These tumors are very hard, and ulceration is superficial. The objective symptoms remain mild for a comparatively long period, but obstipation is usually a troublesome factor. Another type of tumor that remains of low grade malignancy for considerable time is the malignant papilloma. The latter type is easily recognized by the mild induration and the typical appearance when viewed through a proctoscope. The histologic study of these types of tumors suggests grades 1 or 2.

While histologic grading offers the easiest method of estimating the grade of malignancy, it is not always the most accurate. The biopsy submitted may not reveal the true characteristics of the tumor, for in rectal cancers the outlying areas may be altered by secondary *infection and degeneration.* The *most adequate* determination of this important factor is by the combined application of the clinical and histologic studies of the case.

The radiosensitivity of rectal cancer is also a variable factor that is worthy of consideration. In the early stages of disease, highly malignant tumors are also highly radiosensitive. But as the condition progresses, the radiosensitivity is often altered by infection, so that radiosensitive tumors may become radioresistant, on account of this secondary factor. The two types of rectal cancer that are most favorable for radiation therapy are those which are most radiosensitive and those which are strongly radioresistant. The latter require intensive dosage, which is easily supplied by gold filtered emanation seeds. The intermediate grades due to alterations brought about by mixed infection present additional difficulties. The estimation of the degree of radiosensitivity is possible from the calculation of the degree of malignancy, the amount and depth of infection, together with the clinical appearance of the mass. However, a more definite determination of this factor is possible by observing the response of a moderate dosage of external irradiation.

A review of the foregoing factors clearly demonstrates the importance of a careful study of each case of rectal cancer and emphasizes the advantages of selective treatment. While there may be some difference in opinion as to the treatment of choice in patients who are truly operable, I think that every one is agreed that the highest degree of palliation is possible by radiation therapy or radiation therapy and palliative surgery. The advantages afforded by radiation therapy in this disease will depend not only on the factors mentioned but also on the technic and dosage of the physical agents.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. FANSLER AND BINKLEY

Dr. Edward G. Martin, Detroit: I trust that these papers may promote a more uniform and routine examination of the rectum and colon. It is pathetic when one realizes that the majority of rectal cancers, within the reach of one's index finger, are referred to some one who will examine them only after the condition has gone far, far too long to accomplish other than some palliative relief. I question whether a man could justify himself for not making a digital examination at least, in every case that presents any reference to rectal symptoms; I question whether he could defend himself against a malpractice suit. *Dr. Fansler's discussion of rectal polyps is* of great interest, particularly to men who think of the cause as well as the practical treatment of malignant conditions—to the precancer stage and its treatment. Dr. Bloodgood believes that every polyp is potentially malignant and eventually becomes malignant, and he recommends resection in all cases; in other words, radical removal. I think it is such men as Dr. Binkley and such discussions as he has presented that are of the utmost value in promoting new methods; and surely radium and high voltage roentgen therapy are comparatively new methods of treatment. I have seen but little of such work and I am not competent to speak with authority on the subject, but if some one does not take the lead and wade through the storm of objections in attempts to find something that is going to help, that help will never be found; assistance is what such men need. He has not seemed biased in his presentation; he is evidently not offering a single-track cure. I have little faith in high voltage roentgen therapy; have never seen any benefit from it in rectal carcinoma and I know nothing of it in combined treatment as recommended by Dr. Binkley, but I hope something will come of it.

Dr. Descum C. McKenney, Buffalo: Dr. Fansler did not mention one thing that may be the cause of polyps, and that is *Bilharzia*. He mentioned that adenomatous polyps bleed readily. My observation is that single ones in children do, but larger ones in adults may not. They will reach a considerable size before there will be any bleeding at all. In cases of ulcerative colitis, by frequent sigmoidoscopic examinations I have watched the formation of adenomas in two ways. One is by the peeling off of the thickened edge of an ulcer, leaving one edge attached. The other is in the healing of ulcers; the apparently normal columnar epithelium between the ulcers when the ulcers healed and contracted has been squeezed out into the lumen of the bowel, forming a polyp. I have always thought that polypi were due to irritation and inflammation. When, however, polypi are removed and one finds microscopic evidence of inflammation in some and not in others, the question arises whether the inflammation is the cause of or the result of injury. Dr. Fansler has done good work. I hope he will continue it and make a further report.

Dr. C. J. de Bere, Chicago: I have been interested especially in the paper of Dr. Fansler, because in the last three months I have had the opportunity to observe a case which is great proof and justification of what he has just said. A man, aged about 30, complained of bleeding, tenesmus, and some increase in the number of stools. This bleeding was found to be due to a polyp in the rectal ampulla. The polyp was removed and microscopic examination proved that it was nonmalignant. About two months later, he returned again complaining of bleeding, and on proctoscopic examination it was found to come from a soft, oval growth at the base of where the polyp had been removed. A microscopic examination proved that it was adenocarcinoma. Bensaude has brought out the fact that those polyps on a large base with a small pedicle are those which turn malignant, more so than the polyps with a small base and a long pedicle. As far back as 1890, Hartmann and Quénu brought out this fact when they showed the terrible significance of this malignant degeneration by reporting eighteen cases out of twenty-four. In 1907, Doering reported twenty-two out of fifty-seven, and in 1910 Lynch reported forty-six in a hundred. I am sure everybody will agree that there is a definite place for radium therapy in the management and treatment of carcinoma of the rectum. Often the big problem is to keep the patient comfortable and often this cannot be done by surgery. However, I do think that this ought to be done by a man who is skilful and experienced in this line of work, who not only knows all the details of the technic of radium insertion but also is acquainted with the type of tissue to treat and how to treat it.

Dr. Collier F. Martin, Philadelphia: Dr. Fansler's paper is instructive, but there is more I desire to know. Infection, irritation, the mechanics of muscular activity, are factors, but what is that factor that incites cell proliferation? What starts this process in one individual and not in another? I was extremely interested to hear Dr. Fansler's reference to the little indurations—not at the site of the polyps, but in other portions of the bowel—that show a process going forward which might result in multiple polyposis. My experience with cases of multiple adenomas has been rather unfortunate. I have seen many terminate in a malignant condition. I have heard of few cures. Recently I saw a woman, aged 60, who had been bleeding from the rectum. On examination I found two small adenomatous polyps about 12 cm. from the anal margin. Her physician was an electrotherapeutist. He fulgurated them. Six or eight months later, the patient was still bleeding; I found a carcinoma about 2 cm. above the site of the former adenomas. Below that point were two other small polyps of recent origin. Since then she has had the rectum excised and has a good chance of recovering, at least from the operation. I am Presbyterian enough to feel that "what is going to be, will be" and that some people are doomed to death from malignancy no matter what is done. Dr. Binkley's paper impresses me with the fact that the use of any one method in the treatment of a malignant condition is not enough; one kind of surgery is not sufficient, nor is radium, used alone, sufficient. It is not alone what is done but how it is done that brings results. The crying need is for men interested sufficiently in malignant conditions to specialize in saving as many unfortunates as possible. I care not whether he uses one method or many; he must have faith and courage to do everything possible to keep that poor person alive and to make him happy.

Dr. Dudley Smith, San Francisco: The important part of Dr. Fansler's paper is the insistence that careful examination should be made of the rectum and sigmoid for polyps. There is no question that these polyps are much more frequently malignant in their early stages than has been believed in the past. In the last two years I have found six small polyps not larger than the tip of my little finger that were definitely adenocarcinoma. I know that Dr. Binkley is doing particularly good work in advancing the technic of radiotherapy in these cases and that the time may come when this method of treatment and the technic may be improved to the point at which it will be felt that more cases may properly be treated by radiotherapy alone. But I do not believe that that stage has yet been reached, especially in other parts of the country, as much as they have at the Memorial Hospital in New York.

Dr. John L. Jelks, Memphis, Tenn.: I treat many chronic dysenteries, and I find that adenomatosis develops quite frequently in this class of cases; therefore, I would necessarily lean to the theory that carcinoma is thus developed by first, irritation, and hyperplasia, which causes first the nonmalignant growth, and, secondly, the development in the base of that growth. Who started the idea that cancer does not occur in the Negro? It does occur. Not infrequently I have seen cases of cancer in the Negro. I have two such cases now. The only probable cause and field for irradiation in cancer of the anorectal region is in the anal or fixed portion of the alimentary canal; second, as a placebo and for hastening the then inevitable end. In removing one of these little insignificant looking adenomas, one should cauterize its base deep and not be afraid to do it, for it is going to develop cancer.

Dr. W. A. Fansler, Minneapolis: Some of the men have gone so far as to say that all patients with multiple polyposis, unless they die of intercurrent infection, hemorrhage or other complications, sooner or later develop a malignant condition. I think very likely that is a true state of affairs. Dr. McKenney spoke of relative bleeding in children and adults. I think it is simply that in children the polyps are softer and more easily injured than they are in those formed in an adult; in any case there must be injury to the mucosa before they bleed. Some one asked the causes of the formation of adenomatous rectal polyps. I think that these adenomas are caused by irritation, not primarily in the mucosa but in the submucosal tissue, and it is only when the mucosa is pushed up into the lumen of the bowel where it is mechanically irritated that changes in the mucosa itself begin. I do think that these are all potentially carcinomas and should be removed. How this irritation gets underneath the mucosa I do not know. There are certain infections that can get through the epithelial surfaces, which are apparently unabraded. So in the mucosa there must be some microscopic abrasion but not necessarily anything that can be seen with the naked eye.

Dr. G. E. Binkley, New York: Dr. Martin brought out the point that I was trying to emphasize; namely, that as a result of the various factors associated with this disease there is not any one method of treatment suitable for all cases. In order to provide patients with treatment most appropriate for their condition, one must employ various surgical procedures and radiation therapy. Dr. Smith favors the abdominoperineal type of operation. This procedure certainly has its place in the treatment of rectal cancer but is frequently accompanied by a high immediate mortality. By selecting the cases one may often obtain some satisfactory results by less radical methods, a percentage of patients retaining a normal or practically normal terminal gastro-intestinal tract. Dr. Jelks does not appear very happy about radiation therapy in rectal cancer. If he would attend our clinic I am sure we could prove to him that adequate radiation therapy is beneficial rather than detrimental.

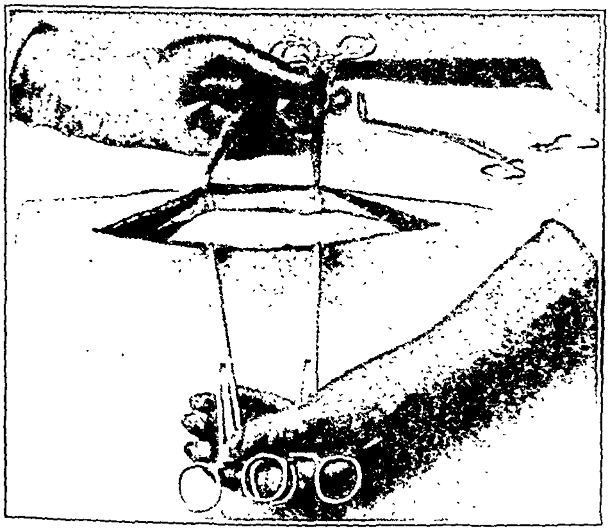
Clinical Notes, Suggestions and New Instruments

PRACTICAL ADVANTAGES OF THE TOGGLESQUEEZE HEMOSTATIC FORCEPS

D. M. Littlejohn, M.D., Pana, Ill.

The handles of hemostatic forceps during major operations have a tendency to stick up in the way and become entangled in the suture material being used. The togglesqueeze hemostatic forceps eliminate to a large extent these operative handicaps, as they lie flat when in use and at right angles with the incision.

Most, if not all, forceps that are now on the market are constructed so that they act on the scissors principle. It is evident, therefore, that the jaws of these instruments operate on the same plane with that of the handles, making it impossible to grasp the peritoneum in abdominal operations without leaving the instrument parallel to, or the handles at a right angle with, the body surface. In either case the operator is materially impeded in his work.



Togglesqueeze hemostatic forceps used as retractors.

The togglesqueeze forceps are so constructed that the opposing jaws are at right angles with the handles and operate in such a manner as to allow the instrument to lie flat when in use. The 90 degree angle of the jaws furnishes a convenient and efficient method of holding an incision open without further need of special retractors. The instrument is easily manipulated, requiring little pressure to lock securely and unlock the handles, which is made possible by the toggle lever construction. The instrument is manufactured from extremely durable material and should be used over a long period without adjustment or repair. In abdominal work from four to eight are usually needed, depending on the length of the incision.

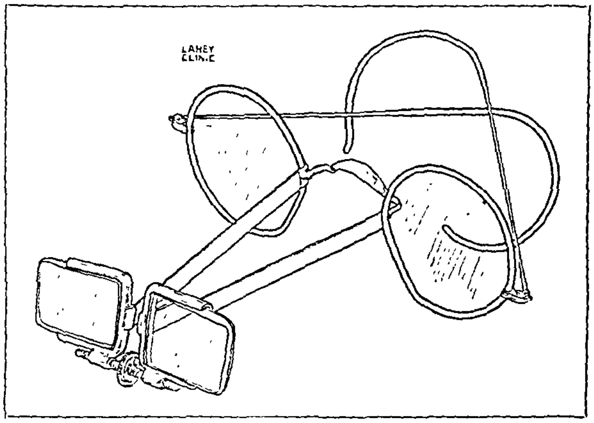
A BINOCULAR LOUPE

Frank H. Lahey, M.D., Boston

The employment of the binocular loupe, illustrated, has been of such service to me that this note is inserted with the idea that it may prove of value to other surgeons.

The illustration shows the frame with the magnifying lenses projected before it. In the frame may be inserted lenses that are demanded by the individual surgeon's eyes, and the magnifying lenses advanced before these may be obtained with the magnification of either two or three times normal size.



Binocular loupe.

The focal range of the lenses is such that there is a safe distance between the lenses and the operative field, so that contamination of the field is avoided.

The lenses have been of particular value to me in searching specimens of thyroid removed for possible parathyroids; these parathyroids to be immediately implanted, as I have suggested, at the time of operation.

The lenses have also been of distinct value in magnifying structures in the region of the inferior thyroid artery which could be demonstrated by magnification to show nerve fibers and the recurrent laryngeal nerve.

The loupe in no way interferes with ordinary vision but makes immediately available double to triple magnification of a small area of the field when necessary.

URTICARIA DUE TO BEDBUG BITES [*]

T. Preston Churchill, M.D., Fort Worth, Texas

A. H. D., a man, aged 29, seen at 2:30 a. m., Sept. 28, 1930, had wheals from 15 to 20 cm. in diameter over the body, legs, arms and face. The eyes were closed from swelling of the lids. These wheals were still growing and showed numerous large pseudopodia around the periphery. In the center of these wheals were small puncture wounds that apparently were due to insect bites or stings. The administration of epinephrine, ephedrine and cold baths caused the wheals and the intense itching that accompanied them to disappear after a few hours. Investigation of the bedding showed numerous bedbugs.

The patient stated that he felt fine when he went to bed. He noticed a slight biting, then intense itching and turned on the light. His eyes swelled shut within a few minutes.

The next morning the left eye was still closed, but the remainder of the wheals had disappeared except for a slight induration around the puncture wounds. Just within the border of the left eyebrow there was a puncture wound. The tissue around this was indurated and reddened.

The past history revealed that the patient had had urticaria on several occasions after eating strawberries for several successive days. He did not recall having been bitten by bedbugs before. There was no history of asthma or hay-fever in his family.

SATURDAY, DECEMBER 27, 1930

THE GRAVES SYNDROME

Nearly a hundred years has elapsed since Graves, in 1835, called attention to a condition commonly termed Graves' disease in English-speaking countries and morbus basedowi on the continent. In more recent years it has been classified with disorders of the thyroid gland under the designation of exophthalmic goiter. The patient who exhibits the cardinal signs has tachycardia, tremor, enlarged thyroid and exophthalmos, together with an increased basal metabolic rate. Errors in diagnosis are, however, not infrequent. One or more of the classic symptoms may be missing; or so-called neurocirculatory asthenia may be confused with the full fledged form of the disease. The reason probably lies in the fact that the latter has a slow evolution that may extend over many years. At a given moment, some of the familiar criteria may be missing or unestablished. Moschcowitz[1] has therefore insisted that it is rather in the summation of the various disease processes than in the rigid determination of one or more criteria that the diagnosis is rendered possible. For this reason the term "syndrome" is more applicable in this connection than the term "disease." It is becoming increasingly apparent, in Moschcowitz's judgment, that in order to be able to classify diseases on a sound biologic basis one must observe disease over a far greater period than one has been accustomed to think. There are probably many maladies regarded as distinct species, which are in reality merely stages of disease processes that have thus far received different names and the relation of which is still unsuspected. Such observations, Moschcowitz adds, are obviously more within the scope of the practitioner than of those who work in institutions or as consultants.

This is merely another way of pointing out that the classification of exophthalmic goiter must be regarded from the dynamic rather than from the static point of view. In other words, it does not merely represent a disease in which various signs are artificially grouped together but rather a biologic series of disorders that have received various names in the past. The natural history of the disease extends over a long period. According to Moschcowitz there is one common denominator for the clinical signs; namely, a neuropathic personality or temperament. This brings to mind the modern conception of a constitutional tendency that predisposes to the Graves syndrome. It is undoubtedly strongly influenced by environmental factors; hence the consideration that the latter deserve in the treatment of patients.

Starting with a constitution of the sensitive type—an emotional personality—the exciting cause of the fully fledged Graves syndrome is, according to Moschcowitz, usually traceable to a psychic insult which is in the nature of a surprise. The dominant inciting factor is likely to be fear. From this point of view the familiar and usually most conspicuous hyperthyroidism is in reality not a primary event in the evolution of the Graves syndrome. Hyperplasia of the thyroid may be lacking; in fact, there appears to be no parallelism between the extent and the intensity of the hyperplasia and the clinical expression of the disease.

A proper diagnosis calls for detailed knowledge of the family history. There are persons who present signs of the neuropathy of exophthalmic goiter but who show little of the physical evidences except perhaps a tachycardia and a tremor. These patients are sensitive, emotional, anxious, tense and irritable, representing what has sometimes been termed autonomic imbalance. In Moschcowitz's words, the touchstone for the diagnostic approach is the reconstruction of the patient's personality or, in other words, his constitution. Of lesser importance, but nevertheless illuminating, is the determination of the exciting psychic insult. The insult is sometimes lacking but the constitution never is. Accordingly the basal metabolism may best be regarded not as a diagnostic sign of the Graves syndrome but as the sign of hyperthyroidism and as the best measure of activity of the disease that one possesses at present.

This point of view aids in interpreting many of the known features of the Graves syndrome. Moschcowitz points out that the racial incidence of the syndrome conforms to what one would expect of ethnologic sensitivity. It is uncommon in races of coarser mental fiber and is common in those of subtler mental reactions and where the strain of existence is keener. The Graves syndrome is apparently a social disease of the higher civilizations. In the development of the influences in which the disorder is likely to develop, such factors as religion, the social and political status, and the availability of the country for sustenance are probably important. The relation of the psyche to the development of the Graves syndrome is shown in the rarity of this disease in children, in whom the adjustable, reasoning and emotive powers are not fully developed.

Surgical intervention is often resorted to in order to decrease the hyperthyroidism. Nevertheless, recurrences are sometimes encountered. These may be better understood if the existence of a potential sensitive constitution is admitted. The latter cannot be eradicated by operation. The constitution, Moschcowitz remarks, persists after any form of treatment, so that cure is never wholly obtainable. The most profound effect of thyroidectomy is on the basal metabolism. Furthermore, as this constitution is profoundly influenced by environment, the treatment of the patient should not cease after thyroidectomy.

THEORIES OF THE ACTION OF ANESTHETICS

Although the applications of anesthetics in medicine and dentistry have been widely extended and the technic of administration steadily improved, surprisingly little advance in the elucidation of the mode of action of this group of pharmacologic agents in the living cells of the organism has been made in late years. In a recent review Henderson[1] has summarized the present status of the theories of narcosis, limiting the discussion to those substances known to depress the central nervous system without inducing permanent change in the nerve cells. Dehydration, asphyxia, changes of surface tension in the cell colloids, adsorption, changes in membrane potential, lipoid solubility and precipitation of cellular constituents have all formed the basis of theories at various times, but with one or two exceptions sufficient evidence has been brought forward to render each postulate largely invalid.

Although by no means the latest of the proposed explanations of narcosis, the theory of Meyer and Overton has received considerable experimental support. In outlining this conception of the action of narcotics, it is stated that those substances which are fat soluble and can thus penetrate the cell wall and distribute themselves within the cell act as narcotics to the living protoplasm. The relative biochemical potency of these compounds depends on their coefficient of partition between the aqueous phase of interstitial fluid and protoplasm and the fatty substances composing the cell. The nerve cells, consisting in large part of lipoids which apparently play an important part in their function, are thus more markedly affected by narcotics than are other cells. Although the basic assumptions of the theory have been criticized adversely, in general it seems the most useful explanation of the phenomenon of narcosis thus far proposed although, even here, it must be admitted that the finer details are missing.

Claude Bernard suggested that those compounds known as narcotics owed their efficiency to the production of a reversible coagulation of the substance of the nerve cell, a theory that has received little favor among students of the general problem. However, Bancroft and Richter[2] have recently adduced data which lead them to consider that this colloid coagulation theory is the correct one. They made use of a model consisting of a carefully prepared culture of yeast cells to which, after preliminary observation under an ultramicroscope, amyl alcohol was added. After a short time brownian movement gradually stopped, then coagulation within the cells became visible, and flocculation of the cells occurred. The narcotized yeast was promptly washed with fresh medium by centrifugating and the culture was observed to return slowly to its original state. The cells exhibited brownian movement once more, were completely peptized, and reproduced as they had done before being narcotized. On the basis of these experiments the Cornell investigators throw the weight of their approval to Claude Bernard's theory of narcosis, pointing out, however, that they believe that the colloids involved are the proteins of the protoplasm rather than the lipoids.

A consideration of the various explanations of the phenomena of narcosis brings out the fact that the evidence for the mode of action of the compounds producing the narcosis in vivo is largely based on biochemical reactions observed in vitro or on relatively simple models, both animate and inanimate. It has been pointed out repeatedly that the physical and chemical equilibriums maintained in the organism during life are extremely complex. A disturbance in one set of factors may bring about a totally unexpected change in a series of other factors. The translation of results obtained with simple biochemical systems to the actions within the body consequently has its limitations. Who can predict when some fact arrived at in this manner will provide the key to a more perfect understanding of even as complex a phenomenon as the reaction of narcotics on the living cell?

IN PRAISE OF CALCIUM

Not until comparatively recent years have students of practical dietetics devoted any serious consideration to the rôle of inorganic nutrients in food. Instinct, which was long lauded as the safe guide to ideal nutrition and which is still heralded even by physicians, has been shown to have its definite limitations in the choice of foods by man. A generation ago Ellen H. Richards, an American pioneer who exhibited zeal for the application of science to daily life, wrote: "It is unsafe to trust the individual to the guidance of the appetite alone, for the reason that this instinct was built up for a condition of existence very different from that which enables the people of this country to indulge themselves today." Realizing the effect that changes in the transportation and distribution of commodities were exerting on the availability of the food supply, she sensed "conformity to scientific laws as the only way to safety."

Among the mineral nutrients, calcium has the dominant place from the standpoint of quantitative needs.

---

[1] Henderson, V. E.: Present Status of Theories of Narcosis, Physiol Rev. **10**: 171 (April) 1930.

[2] Bancroft, W. D., and Richter, G. H.: Proc. Nat. Acad. Sc. **16**: 573, 1930.

It constitutes about 1.5 per cent of the body—nearly 3 pounds in the case of an adult man. Of this, over 99 per cent is present in the bones. The latter are today a recognized storehouse for calcium, this element having a far greater degree of "mobility," or freedom of liberation and transport, than is generally suspected. The best estimates currently available suggest the advisability of a daily intake of 1 Gm. or more of calcium in order to prevent loss of the indispensable element. Although calcium is abundantly present in nature, it is unevenly distributed in human foods; in fact, most of them are characterized by a paucity of calcium. For example, the cereal grains, tubers, meats, fish and fruits, all of which are prominent in the dietary of omnivorous man, are comparatively poor in calcium. On this account Sherman has remarked that the "ordinary mixed diet" of Americans and Europeans, at least among dwellers in cities and towns, is probably more often deficient in calcium than in any other chemical element.[1]

A recent investigation in the department of chemistry at Columbia University by Sherman and Booher [2] has stressed anew the relation between the calcium intake and the calcium content of the growing body. Animals with comparable heredity and nutritional backgrounds and with all factors other than food maintained strictly uniform were supplied with food of differing calcium content. It was thus found that individuals otherwise well nourished but with low calcium intake do grow up with calcium-poor bodies. It is also evident, as a result of these experiments, that the body may be able to retain calcium at a subnormal rate on a diet relatively poor in calcium and so at an abnormally late age may finally come to approximate a normal percentage of body calcium. Sherman and Booher therefore insist that application of these observations to the problem of normal human nutrition should prevent any relaxation of attention to adequate calcium supply in the food. Vitamin D as a "calcium-mobilizing" factor is not a substitute for calcium. The body at birth has a low calcium content and its normal development involves a large increase not only in the amount but also in the percentage of calcium that it contains, and so requires a liberal supply of calcium in the food. Otherwise the growing body remains calcium poor, even though it shows every external appearance of being well nourished.

Milk is ordinarily looked on as the superlative source of calcium, and with due justice. During the World War the U. S. Food Administration insisted, in its educational texts,[3] that the free use of milk tends to build up a strong nation. It taught that the importance of milk can hardly be overemphasized, since there is no other food so vital to national health and efficiency. Some writers have gone so far as to assert that calcium is not advantageously absorbed from most foods other than milk, and particularly not from artificial inorganic supplements of calcium to the diet. Recent studies by Potter and Kramer [4] at the Kansas Agricultural Experiment Station, Manhattan, make such generalizations untenable. Healthy women ingested alternately milk and calcium lactate under otherwise comparable dietary conditions in which the items mentioned supplied two thirds of the available calcium. They appeared to utilize the inorganic calcium as effectively as the calcium of raw milk.

Current Comment

THE VITAMIN A OF BUTTER

Next to milk, which is often described as "the most nearly perfect food," probably no single dietary component has received more laudatory mention from dietetic experts than has butter. This has not been due primarily to the high energy value of the milk fat, for many fats and oils of equal food fuel value and ready digestibility are available everywhere at far lower prices than butter of good quality commands. The palatability and characteristic flavor commend it to many persons; but the student of nutrition is likely to refer first of all to the comparative richness of good butter in vitamin A. In the long-standing debates between the advocates of margarines of varied sorts and the promoters of butter, one no longer hears of complaints regarding the insanitary conditions under which the "butter substitutes" were alleged to be manufactured, or the indigestibility of the substitute fats, or their hygienic qualities. Butter is today lauded primarily because of the indispensable vitamin that it contains; and the producers of margarines have not been slow to venture to incorporate vitamin A into their "artificial" products as effectively as possible. As Sherman [5] has pointed out, legislation in the United States has generally been such as to discourage the oleomargarine industry, and our present knowledge of the wide difference in vitamin value between butter and oleomargarine, he adds, naturally and properly tends to increase the preference of consumers for butter. According to Sherman it appears safe to say that none of the butter substitutes approach good butter in vitamin value and that butter, even when of poor quality, is likely to be much richer in vitamin than any other commercial form of food fat. The latest developments in the scientific study of vitamin B have an unexpected bearing on the possible food value of butter fat. It seems to be clearly established that the physiologic action of vitamin A can be reproduced, or at least closely simulated, by administration of the plant pigment carotene [6] (or carotin, as it is usually designated by American chemists). This helps to explain the nutrient virtues conspicuous in foods that are rich in carotinoid pigment. Morton and Heilbron[7] of the University of Liverpool have recently demonstrated that the nonsaponifiable matter from butter contains both carotene and vitamin A. The natural color of butter thus endows it with unexpected physiologic virtues not formerly suspected.

THE POTENCY OF EPINEPHRINE

In former generations the great potency of minute quantities of certain drugs and poisons elicited the interest of professional students and aroused general curiosity. The realization that less than a grain (64 mg.) of some of the alkaloids may constitute a fatal dose for man and that glyceryl trinitrate, for example, in doses of less than 1/100 grain—less than a milligram—is pharmacologically potent and therapeutically useful awakened varied conjectures. Of late, these "wonders of science" have been supplemented by demonstration of the surprising functional potency of substances that are not ordinarily foreign to the body, as are drugs or poisons, but occur as components of food or the secretions of some of the glands. Thus the digestive enzymes can transform many thousand times their weight of specific complex foodstuffs into smaller chemical molecules. There is barely one-tenth ounce of iron in the entire body of a full grown person, or 1 part in 25,000 by weight; yet it is of importance not only in maintaining the integrity and functions of the blood but undoubtedly also in other "vital" activities of living cells. The total wastage of iron incident to the "wear and tear" of the tissues probably does not exceed one-fifth grain of iron, the equivalent of little more than a trace of iron rust. In a recent lecture in London, Professor de Quervain[8] of Berne, who has had vast experience in the prophylaxis of goiter, insisted that the physiologic intake of iodine should not exceed 0.5 mg. daily. In fact, this indispensable element is present in the body in amounts approximating only 0.0004 per cent of the body weight. Deprivation of the physiologic minimum spells distress and, in time, disease. The dosage of the vitamins is still too inadequately known to permit more than rather uncertain statements. There is no doubt, however, that one part of vitamin D in many million parts of the body can function effectively. Cori and Buchwald[9] of the State Institute for the Study of Malignant Disease, Buffalo, have recently secured information regarding one of the best known hormones, the epinephrine of the adrenal structures. This substance was injected intravenously into normal men for a period of thirty minutes; 0.00005 mg. for each kilogram per minute proved to be the lowest rate of injection that still caused a rise in blood pressure, blood lactic acid and basal metabolism; 0.000025 mg. for each kilogram per minute was still able to increase pulse rate, respiration and blood sugar. After the administration of epinephrine, the pulse rate, respiration and blood pressure returned to the original level in from five to ten minutes, and basal metabolism in fifteen to thirty minutes, while generally more than thirty minutes was required for blood sugar and blood lactic acid. These potencies are somewhat greater than the lowest effective dosages found in some of the laboratory animals. The vascular system of man is therefore decidedly more sensitive to epinephrine. This, Cori and Buchwald aver, is undoubtedly the reason why a subcutaneous injection of epinephrine may produce a rise in blood pressure in man when it fails to do so in other species.

Association News

CONTRIBUTIONS TO PERSHING MEMORIAL

Numerous physicians have sent in their contributions to the fund for the decoration and maintenance of the Medical Salon in Pershing Hall in Paris. The total sum thus far received is $721.10. It is hoped that many additional contributions will be received. The total sum to be raised is $10,000. The individual contributions here recorded represent less than 10 per cent of the total amount required. Group contributions by medical societies, hospital staffs, and other medical organizations will be especially welcomed. A supplementary list of the contributors up to noon of December 22 follows:

J. D. Pettet, M.D., Arcadia, Kan.
Oscar A. Mockridge, M.D., Montclair, N. J.
Carl V. Vischer, M.D., Philadelphia
Thomas S. Roberts, M.D., Minneapolis
H. T. Partree, M.D., Torrington, Conn.
Herman B. Slotkin, M.D., Philadelphia
L. B. Drake, M.D., Ogdensburg, N. J.
W. Houston Toulson, M.D., Baltimore
C. A. Earle, M.D., Des Plaines, Ill.
Charles S. Bumgarner, M.D., Davenport, Wash.
D. G. Smith, M.D., Nashua, N. H.
George D. Jeffers, M.D., Parkersburg, W. Va.
Leo A. Newcomb, M.D., Montpelier, Vt.
Joseph Aspray, M.D., Spokane
Edwin O. Swanson, M.D., St. Paul
Daniel R. Robert, M.D., New Lebanon Center, N. Y.
William Petry, M.D., Newark, N. J.
J. H. Baker, M.D., La Crosse, Kan.
C. L. Garris, M.D., Berlin, N. H.
Roy P. Forbes, M.D., Denver
M. C Johnston, M.D, Aberdeen, S D.
J. D. Madison, M.D., Milwaukee
William H Dudley, M.D., Los Angeles
W H. Roberts, M D., Pasadena, Calif.
Lyman S. Hall, M D, Broken Bow, Okla.
Augustin V. Mendel, M D., Newark, N J
Edward C. Klein, Jr., M.D., Newark, N. J.
Richard P. Strong, M.D., Boston
Fred C. Sabin, M.D., Little Falls, N. Y.
Walter A. Sherwood, M.D., Brooklyn
Mark H. Wentworth, M.D., Boston
Solomon Hermann, M.D., Brooklyn
Jacob M. Cahan, M.D., Philadelphia
E. L. McCrea, M.D., Table Rock, Neb.
Henry R. Rado, M.D., Mt. Vernon, N. Y.
Hermann Grad, M.D., New York
A. L. Van Meter, M.D., Stockton, Calif.
Carl H. Schnaer, M.D., Chicago
Hyman Green, M.D., Boston
Mark Sutphin, M.D., Logan, W. Va.
John E. Boyd, M.D., Jacksonville, Fla.
Horace Reed, M.D., Oklahoma City
P. E. Rossiter, M.D., Lee Hall, Va.
Edgar W. Young, M.D., Petersburg, Va.
R. B. Rossell, M.D., Buffalo
Paul M. Patterson, M.D., Hollywood, Calif.
E. B. Schrock, M.D., Seattle
C. A. Kirkley, M.D., Los Angeles
W. H. Bunn, M.D., Youngstown, Ohio
Harry Gold, M.D., New York

Marion County Medical Society, Knoxville, Iowa
J. William Ledbury, M.D., Uxbridge, Mass.

MEDICAL BROADCAST FOR THE WEEK

American Medical Association Health Talks

The American Medical Association broadcasts at 10 a. m. on Monday, 10.15 on Tuesday, 10:30 on Thursday and 10 on Saturday, over Station WBBM (770 kilocycles, or 389.4 meters).

The program for the week is as follows:

December 29. The Story of Anesthesia.
December 30. Radium Fakes.
January 3. Climate and Tuberculosis.

Five minute health talks may be heard over the Columbia Broadcasting System daily except Sundays and holidays, from 12 to 12:05 p. m.

The program for the week is as follows:

December 29 Concerning Germs.
December 30 Concerning Germs
December 31 Endemic Diseases.
January 2. Cold Facts.
January 3. Winter Vigor

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest: such as relate to society activities, new hospitals, education, public health, etc.)

INDIANA

Personal.—Dr. Theodore E. Collier was guest of honor at a reception given by citizens of Brook in recognition of his thirty-six years' practice in the community and active participation in civic enterprises; the celebration was held on his sixty-eighth birthday. Dr. Collier was presented with a book containing the autograph of each guest.

Society News.—The fifteenth annual meeting of the Indiana Society for Mental Hygiene was held, December 8, in Indianapolis. Among the physicians who appeared on the program were: Drs. Louis P. Harshman, Fort Wayne, who spoke on "Training for Teachers of Special Classes"; Charles C. Wilson, Evansville, on "Special Provision for Retarded Children"; Harold S. Hulbert, Chicago, on "School Clinics"; Frank F. Hutchins, Indianapolis, on the teaching of mental hygiene in professional schools; Helen P. Langner, Indianapolis, on "Teaching Mental Hygiene in a Training Course for Social Workers"; William F. King, Indianapolis, on "Magnitude of Mental Hygiene as a Public Health Problem"; Louis F. Ross, Richmond, on "Organization of the Mental Hospital and Its Rôle in Community Life," and Sidney D. Wilgus, Springfield, Ill., on "Organization of Community Facilities for the Prevention, Care and Treatment of Nervous and Mental Diseases."——Dr. Harry Malcome Hedge, Chicago, addressed the La Porte County Medical Society, November 20, at La Porte on "Treatment of Common Skin Diseases," illustrated.——The Hamilton County Medical Society was addressed, November 11, at Arcadia by Dr. Robert M. Moore, Indianapolis, on "Internal Medicine."——At the annual election of the Indianapolis Medical Society, December 2, in Indianapolis, Dr. Edmund D. Clark was made president, and Dr. Chester A. Stayton, secretary.

MARYLAND

Hospital News.—A department of oncology has been opened at the University of Maryland Hospital, Baltimore. The work of the department, which is a subdepartment of surgery, has been divided into two groups, one for the treatment of gynecologic conditions and the other for the treatment of general surgical problems. Dr. John Mason Hundley, Jr., is in charge of the gynecologic section and Dr. Grant E. Ward will be in charge of the general surgical group. Every facility for the management of neoplastic diseases will be available and will include surgery, electrosurgery, radium and high voltage roentgen therapy. Private as well as nonpaying patients will be received.

Society News.—At a conference on public health under the auspices of the Maryland League of Women Voters in Baltimore, December 4-5, Dr. William H. Welch presided; among the speakers and subjects on the program were Drs. Samuel Wolman, the tuberculosis problem in Maryland; John Whitridge Williams, maternal and infant hygiene, and Josephine Baker, school hygiene. Dr. Haven Emerson, New York, spoke at the evening session on "Medical Economics."——Dr. Wilbur A. Sawyer, associate director, International Health Division, Rockefeller Foundation, gave one of the De Lamar lectures in hygiene on "Recent Progress in Yellow Fever Research," December 9, at the Johns Hopkins University School of Hygiene and Public Health.

De Lamar Lectures at Johns Hopkins.—The following De Lamar lectures will be given on the dates indicated at the School of Hygiene and Public Health of Johns Hopkins University:

Dr. William Lloyd Aycock, assistant professor of preventive medicine and hygiene, Harvard University Medical School, January 6, "The Epidemiology of Poliomyelitis."

Raymond Adams Dutcher, professor of biochemistry, Pennsylvania State College, State College, Pa., January 27, "Factors Influencing Vitamin Distribution in Foods."

Dr. Thomas Parran, Jr., commissioner of health, state of New York, March 3, "Venereal Diseases."

Dr. William B. Wherry, professor of bacteriology and hygiene, University of Cincinnati College of Medicine, March 31, "Hypersensitivity to Bacterial Proteins and Its Rôle in Susceptibility and Immunity."

Dr. George F. McCleary, deputy senior medical officer, Ministry of Health, England, April 14, "The Prevention and Cure of Narcotic Drug Addiction."

MICHIGAN

Dr. Ewing to Give Beaumont Lectures.—Dr. James Ewing, professor of pathology at Cornell University Medical College, New York, will give the tenth annual Beaumont lectures, January 26-27, in Detroit, under the sponsorship of the Wayne County Medical Society. The titles of Dr. Ewing's lectures will be "Causation of Cancer," "Diagnosis of Cancer" and "Treatment of Cancer."

Society News.—The Oakland County Medical Society was addressed, November 18, at Pontiac by Dr. Bertil T. Larson on "The Diagnosis of Mastoiditis," and Dr. Harold A. Furlong, "Early Diagnosis of Pregnancy by Means of the Aschheim-Zondek Reaction."——Dr. Walter C. Alvarez, Rochester, Minn., addressed the Washtenaw County Medical Society, December 13, on "Problems of Gastro-Enterology."——Dr. Arthur C. Curtis, Ann Arbor, addressed the Gratiot-Isabella-Clare Counties Medical Society, November 13, on "Laboratory Methods in Everyday Diagnosis."——Dr. Chester W. Waggoner, Toledo, addressed the Wayne County Medical Society, Detroit, December 2, on "Chronic Duodenal Stasis."

Personal.—Reuben L. Kahn, Sc.D., has returned from the serologic conference at Montevideo, Uruguay, September 15-25, where he demonstrated the Kahn reaction.——Dr. Harry T. Gray recently resigned as city health officer of Owosso and has been succeeded by Dr. Walter E. Ward.——Dr. Jacob D. Brook, Grandville, was elected full-time health officer for the Kent County Health Unit, December 9; the new unit will be instituted, January 1.——Dr. Reuben Peterson, Ann Arbor, has resigned as professor of gynecology and obstetrics at the University of Michigan Medical School, Ann Arbor. A dinner was given in honor of Dr. Peterson, December 1, by the Detroit Obstetrical and Gynecological Society.

Proposal to Limit Use of Roentgen-Ray Apparatus Defeated.—On the recommendation of the Wayne County Medical Society, the Common Council of the City of Detroit declined, November 24, to pass an ordinance proposing to prohibit the use of electrical vibrating equipment for roentgen-ray machinery between 7 p. m. and midnight. It was urged by proponents of the ordinance that such use interfered with radio reception. Resolutions adopted by the medical and civic relations committee and presented to the council pointed out that the use of diathermy and roentgen-ray apparatus during the hours from 7 p. m. to midnight is for the benefit of the public, which must be served in accidents and therapy cases during these hours; and that in 1,000 investigated cases the whole twenty-four hours' use of diathermy and roentgen-ray apparatus represents less than 2 per cent of all interference in radio reception, which would mean that interference between 7 p. m. and midnight would be of negative quantity.

MINNESOTA

License Revoked.—The license to practice medicine of Dr. Philip Mueller, Minneapolis, was revoked, December 2, by the Minnesota Board of Medical Examiners after he had been found guilty of habitual indulgence in morphine sulphate. Dr. Mueller served two years in the state penitentiary at Stillwater after he was convicted, June 6, 1913, of manslaughter following the death of a woman on whom an abortion had been performed.

"Specialist" Placed on Probation.—According to the secretary of the State Board of Medical Examiners, Ada Winchel, who was said to maintain offices in St. Paul under the title of "Arabian rheumatic specialist," was sentenced, December 8, by Judge R. D. O'Brien, of the district court, to serve a term not to exceed one year in the women's reformatory at Shakopee. The charge was that of violating the basic science law. The sentence was suspended and the woman was placed in the custody of a probation officer on condition that she close her office and refrain from practicing in any way in Minnesota.

NEW YORK

Dr. Ramsdell Resigns as Health Officer.—Dr. Edwin G. Ramsdell has resigned as municipal health officer of White Plains, effective January 1, after fifteen years' service and will be succeeded by Dr. Edward H. Marsh, secretary of the New York State Department of Health. The White Plains health work is under the control of the Westchester County Health Commission. White Plains is said to be the first of four cities —White Plains, Yonkers, Mount Vernon and New Rochelle—

to enroll in the county health unit, which is administered by both the county and the state, each of which pays half the operating expenses. Dr. Matthias Nicoll, Jr., resigned, January 16, as state health commissioner in order to accept the position of health commissioner of the newly created Westchester County Health Unit. Dr. Ramsdell will retire from active public health work.

Licenses Revoked and Suspended.—The Board of Regents of the University of the State of New York, reports that at a meeting, November 21, five physicians were disciplined as follows:

Dr. Philip Korn, New York, license revoked for performing a criminal abortion.
Dr. Stephen J. Spencer, Buffalo, license revoked for fraud and deceit in the practice of medicine.
Dr. Joel Grosner, New York, license revoked because he had been found insane.
Dr. Alexander Angus, New York, license suspended for six months for aiding and abetting an unlicensed practitioner.
Dr. Irving P. Withington, New York, ordered to appear before the Grievance Committee of the Board of Regents early in January for censure and reprimand.

New York City

Personal.—W. Frank Walker, D.P.H., has been appointed to the staff of the Commonwealth Fund; the statistical service of the fund, recently set apart from the division of publications, will be developed into a separate division and will be headed by Dr. Walker and will continue the established services to child guidance clinics.

New York to Have Behavior Clinic.—A behavior clinic to study and help adjust cases of retarded, maladjusted, truant and otherwise delinquent children is soon to be opened under the direction of the public school system of New York. An appropriation of $100,000 asked for by the board of education has been approved by the board of estimates, it is reported. There will be two units: a main clinic centrally located for diagnosis and treatment of acute and chronic cases of maladjustment and behavior problems arising in schools among older pupils; and a branch for investigations along diagnostic and preventive lines among younger children. The main clinic will be under the supervision of an expert psychiatrist aided by a pediatrician, case workers and psychologists. A smaller but similar staff will be in charge of the branch.

Society News.—Dr. Harold Neuhof of Mount Sinai Hospital will give the second lecture in pediatrics and cognate sciences, January 6, on "Surgical Treatment of Suppurative Lesions of Lung and Pleura."——"Schistosomiasis in Porto Rico" was the subject of an illustrated address given by William A. Hoffman, D.Sc., assistant professor of parasitology, School of Tropical Medicine of the University of Porto Rico, December 22, at Mount Sinai Hospital.——Dr. William P. Healy addressed the Medical Society of the County of New York, December 22, on "Present Status of the Diagnosis and Treatment of Cancer."——At the meeting of the Yorkville Medical Society, December 15, Dr. Herman O. Mosenthal presented an address on "Clinical Aspects of Nephrosis (Diabetes Albuminuricus)," and Dr. Priscilla White, Boston, "Care of the Diabetic Child."——Dr. Charles Norris spoke on "The Medical Examiner's Office in Its Relation to the Physician," and Dr. Bernard Glueck, Ossining, on "Recognition and Management of Every-Day Problems in Mental Hygiene" before the New York Physicians Association, December 17.——Dr. Joseph Colt Bloodgood, Baltimore, will read a paper on "Breast Tumors in Relation to Chronic Cystic Mastitis," January 5, before the Medical Society of the New York Polyclinic Medical School and Hospital.——The Flatbush Medical Society was addressed, December 12, by Drs. Walter D. Ludlum on "The Attitude of Organized Medicine to the Economic Problems of the Doctor," and John J. A. O'Reilly, "The Effect of Political Control on the Economic Status of Medicine."——The German Medical Association of New York celebrated its seventieth anniversary with a dinner, December 6. Drs. William H. Welch, Baltimore, and John A. Hartwell were honor guests.

OKLAHOMA

Society News.—Among others addressing the Oklahoma City Clinical Society, November 5-7, were Dr. Francis M. Pottenger, Monrovia, Calif., on "Importance of Visceral Neurology in General Medicine," and Dr. Melvin S. Henderson, Rochester, Minn., on fractures. Dr. Irving W. Potter, Buffalo, conducted a clinic in obstetrics.——Dr. John T. Wharton, Durant, gave an address on "Ether Anesthesia" and Dr. Joseph S. Fulton, Atoka, read a paper on the organization and accomplishments of the medical profession before the Bryan County Medical Society, November 18.——Drs. Rex G. Bolend, Oklahoma City, and Shade D. Neely, Muskogee, addressed the Muskogee County Medical Society, November 16, on "Features in Diagnosis and Treatment of Syphilis" and "Prostatitis, Nonvenereal," respectively.

GENERAL

Grants to Aid in Research.—The Committee on Scientific Research of the American Medical Association invites application for grants of money to aid in research on problems bearing more or less directly on clinical medicine. Preference is given to requests for moderate amounts to meet specific needs. For application forms, address the committee at 535 North Dearborn Street, Chicago.

Another Medical Journal.—The *American Journal of Orthopsychiatry*, which made its first appearance in October, will be published quarterly by the American Orthopsychiatric Association and contain the proceedings of the annual meetings. The journal is devoted to the publication of articles covering any and all of the issues involved in the study and treatment of behavior difficulties, more especially those illustrating the dynamic interrelationships within the human personality. Dr. Lawson G. Lowrey, New York, is editor.

News of Epidemics.—Thirty-nine cases of scarlet fever were reported in Johnstown, Pa., during November and up to December 4.——More than 100 cases of scarlet fever had been reported in Indianapolis from October to December 4.——An outbreak of forty-two cases of diphtheria occurred in an elementary school in Schenectady, N. Y., shortly after the opening of the school year; thirty children were reported to be still in the city isolation hospital, November 19.——More than 100 cases of measles were reported in Iron Mountain, Mich., up to November 28.——Twenty-one cases of tularemia were recorded in Illinois during the week of December 1.

Society News.—At the autumn meeting of the Society for the Study of Asthma and Allied Conditions, December 6, the speakers with their subjects were: Drs. Joseph Harkavy, New York, "Infectious Asthma and Its Relationship to Chronic Sinus and Pulmonary Infections"; Arthur F. Coca, "Studies of Artificial Complex Antigens," and Henry W. Straus, Brooklyn, "Artificial Sensitization of Infants to Poison Ivy."——The annual meeting of the American Social Hygiene Association will be held, January 23-24, in New York with headquarters in the Hotel Pennsylvania. The tentative program includes papers by Harry E. Barnard, Ph.D., director of the president's White House Conference on Child Health and Protection, on "The White House Conference," and Henrietta Additon, director, New York City Crime Prevention Bureau, "The Prevention of Crime and Delinquency."——At the annual meeting of the Seaboard Medical Association of Virginia and North Carolina, December 5, Dr. James H. P. Culpepper, Norfolk, was elected president, and Dr. Clarence Porter Jones, Newport News, secretary, reelected. The next annual convention will be held in Suffolk, beginning the first Tuesday in December, 1931.——The eastern section of the American Laryngological, Rhinological and Otological Society will meet in Atlantic City, January 5.

The Danger from Methanol.—Regarding the statement issued December 6 by the Bureau of Mines on the effect of methanol antifreeze on health, Surg. Gen. Hugh S. Cumming, when asked, said that the U. S. Public Health Service had kept in touch with the observations being made by the Bureau of Mines. He felt there was need for the immediate release of information which would protect the general public. It appeared from the study so far that there was much more danger from exhaust gas (carbon monoxide) than could possibly come from methanol when used strictly as an antifreeze liquid in automobiles. The greatest danger, he said, is that some one might drink methanol, especially in view of its being used in place of ordinary denatured alcohol as an antifreeze, and in view of its other name, methyl alcohol. Methanol when taken internally is more certainly poisonous and more highly fatal than any denatured alcohol. According to press accounts, such poisoning has recently occurred in Pennsylvania. Another danger is in the use of methanol in shellacs which might be applied over considerable surfaces without adequate ventilation. The presence of the coloring matter as recommended by the Bureau of Mines and the addition of 23 per cent water as at present dispensed, guard antifreeze methanol against such dangerous use. A complete study is advisable as to how far methanol can be used safely in other ways; in the meantime, the surgeon general recommends that methanol be used by the general public as an antifreeze only, and that the precautions advised by the Bureau of Mines be strictly observed.

Report of Prohibition Commissioner.—The annual report of the Commissioner of Prohibition for the year ended June 30, made public December 8, shows that 191,859,342.42 proof gallons of alcohol was produced during the year. The decrease of nearly nine million gallons over the previous year was attributed to the current recession in industries using alcohol. There was withdrawn from bond, for denaturation, 181,601,420.34 proof gallons of alcohol and rum, also a decrease of about a million gallons; 105,787,537.72 wine gallons of denatured alcohol was produced. There are only two completely denatured alcohol formulas authorized at present. The most interesting development in the industrial alcohol trades for many years is the process of making synthetic ethyl alcohol from ethylene gas. The chemical corporation, granted a permit for that purpose during the year, will take rank with the large producers of alcohol now operating. The amount of denatured alcohol used for the manufacture of liniments and lotions was 1,113,293 wine gallons; for the making of drugs and medical supplies, 3,522,171 gallons, and for bathing alcohol, 1,071,776 gallons. At the end of the fiscal year there were 110,319 permits which had been issued to physicians, dentists, veterinarians, and so forth, and 2,773 permits to hospitals. The amount of whisky for medicinal purposes for which permits were issued for the year ending Dec. 31, 1930, was 2,104,000 proof gallons and the amount of brandy and rum for medicinal and general nonbeverage use was 50,000 proof gallons each. The manufacture of medicinal whisky was allotted to twelve warehousemen who were distillers or successors to distillers. These were the first spirits produced for medicinal purposes for nearly nine years. This report covers the last year when the administration of the prohibition laws were under the commissioner of prohibition. The Bureau of Prohibition, which was reorganized under an act of Congress, was transferred to the Department of Justice, July 1, 1930.

Bequests and Donations.—The following bequests and donations have recently been announced:

University of Chicago, $200,000, of which one half is for the Frank Billings Medical Clinic and the other half for the general endowment fund of the university; Children's Memorial Hospital, $200,000; Visiting Nurse Association of Chicago, $25,000, and the United Charities of Chicago, $25,000 by the will of the late Thomas D. Jones.

Jewish Charities, $25,000; United Charities and Catholic Charities, each $10,000, and Mercy Hospital, Chicago, $10,000 by the will of Frederick I. Mandel.

A trust fund of $235,000 to provide for medical research in the prevention of blindness is created in the will of Mrs. Louis Chapin Norton, Provincetown, Mass.

Beverly Hospital, Beverly, Mass., $15,000 by the will of William C. Loring as a memorial to his sister.

Mount Sinai Hospital, New York, $20,000 by the will of the late Emanuel Van Raalte.

Philadelphia Home for Incurables, the residue of her estate, approximately $5,000, by the will of the late Mrs. Carrie Hammel.

New York Post-Graduate Medical School Hospital and Fifth Avenue Hospital, New York, each $25,000, and Presbyterian Hospital, New York, $100,000 by the will of Mrs. Emma Robbins.

Columbia University, $500,000 from Edward S. Harkness to supplement his original gift of $2,000,000 for a residence hall at the Medical Center.

Chicago Memorial Hospital, about $750,000; United Charities, $25,000; Illinois Society for the Prevention of Blindness, $10,000, and Jackson Park La Rabida Sanatorium, $10,000, all of Chicago, by the will of the late George H. McCammon.

West Philadelphia Hospital for Women, Philadelphia, $5,000 on the death of her sister, Sarah Borton Peck, by the will of the late Dr. Elizabeth L. Peck.

New York Post-Graduate Hospital, $10,000, and Memorial and Reconstruction hospitals, each $5,000 by the will of the late William Archer Purrington.

North Woods Sanatorium, Saranac, N. Y., Montefiore Hospital and Hospital for Joint Diseases, New York, each $240,652, and Mount Sinai Hospital, $15,000 by the will of the late Mrs. Minnie Hayman.

New York Orthopedic Hospital, New York, $50,000 by the will of the late Marion Borden, Middletown, N. Y.

Mount Sinai Hospital, New York, $7,500 by the will of the late Mrs. Selina E. Sommerfield.

Light House of the New York Association for the Blind, $250,000 by the will of the late Charles L. Denison, Saddle River, N. J.

Federation of Jewish Charities, $2,500; Jewish Hospital Association, $1,500; Mount Sinai Hospital, Philadelphia, $1,500, and Eagleville (Pa.) Sanatorium, $1,000 by the will of the late Adolph Loeb.

Beekman Street Hospital, New York, $50,000 by the will of the late William Hamlin Childs.

Presbyterian Hospital, New York, $15,000 by the will of the late Clara Beales Obrig.

St. Vincent's Hospital, Manhattan, $10,000 by the will of the late Mrs. Margaret O'Connor Kieley.

Ernest V. Cowell Memorial Hospital, Berkeley, Calif., $1,595 from alumni of the University of California for furnishings and equipment.

Truesdale Hospital, Fall River, Mass., endowment of $500,000 by Earle P. Charlton.

Mount Sinai Hospital, New York, $10,000 by the will of Laurence Davies.

St. Mary's Hospital, Hoboken, N. J., $15,000 by the will of the late Gustave Vintschger.

Presbyterian Hospital, Newark, N. J., $25,000 by the will of the late Robert Crabb.

Southside Hospital, Bay Shore, $10,000; Memorial Cancer Hospital, $5,000; Woman's Memorial Hospital, $15,000, and St. Luke's Hospital, all of New York, the entire residuary estate of Mrs. Jane E. Andrews.

People's Hospital, Peru, Ill., $3,000 by the will of Louise Loekle.

Manhattan Eye, Ear and Throat Hospital, New York, $100,000 by the will of Lloyd W. Seaman.

Carlisle Hospital, Carlisle, Pa., $10,000 from the estate of Noah Hoover of Franklin County.

Medical Bills in Congress.—S. 5064, introduced by Senator Broussard, Louisiana, proposes to authorize the erection of an addition to the veterans' hospital at Alexandria, La. S. 5071, introduced by Senator Smith, South Carolina, proposes to authorize the erection of a veterans' hospital in South Carolina. S. 5073, introduced by Senator Glenn, Illinois, and H. R. 14574, introduced by Representative Igoe, Illinois, propose to authorize an appropriation not to exceed $2,000,000 for construction at the Edward Hines, Jr., Hospital, Hines, Ill. S. 5074, introduced by Senator Glenn, Illinois, proposes the erection of an addition to the veterans' hospital, numbered 105, Chicago. S. 5081, introduced by Senator Robinson, Arkansas, proposes the erection of a 400 bed veterans' hospital in Arkansas. S. 5091, introduced by Senator Johnson, California, proposes to authorize the erection of an addition to the veterans' hospital at Livermore, Calif. S. 5092, introduced by Senator Johnson, California, and H. R. 14691, introduced by Representative Englebright, California, propose to erect a veterans' hospital in the inland part of California. S. 5093, introduced by Senator Johnson, California, proposes to erect a veterans' hospital in the southern part of California. S. 5102, introduced by Senator Carey, Wyoming, proposes to authorize the erection of a veterans' hospital at or near Thermopolis, Wyo. S. 5113, introduced by Senator Vandenberg, Michigan, and H. R. 14572, introduced by Representative Hooper, Michigan, propose to authorize the erection of an addition to the veterans' hospital, numbered 100, at Camp Custer, Mich. S. 5140, introduced by Senator Steck, Iowa, and H. R. 14453, introduced by Representative Campbell, Iowa, propose to authorize the erection of a veterans' hospital in Iowa. S. 5145, introduced by Senator Shipstead, Minnesota, proposes the erection of a convalescent hospital at the military reservation at Fort Snelling, Minn. H. R. 13568, introduced by Representative Ludlow, Indiana, proposes to authorize the erection of an addition to the veterans' hospital in Indianapolis. H. R. 14247, introduced, by request, by Representative Christopherson, South Dakota, proposes to increase the efficiency of the Veterinary Corps of the regular army by providing that officers shall be initially appointed in the grade of first lieutenant and shall be promoted after completion of the same periods of service as now provided by law for promotion of officers of the medical and dental corps of the regular army. H. R. 14443, introduced by Representative Crail, California, proposes to authorize the construction of additional hospital facilities at the Pacific branch of the National Soldiers' Home, Los Angeles County, Calif. H. R. 14457, introduced by Representative Evans, California, proposes to authorize the erection of an addition to the veterans' hospital, numbered 104, at San Fernando, Calif. H. R. 14561, introduced by Representative Hall, Mississippi, proposes to authorize the erection of an addition to the veterans' hospital at Gulfport, Miss. H. R. 14562, introduced by Representative Hull, Tennessee, proposes to authorize the erection of a veterans' hospital in middle Tennessee. H. R. 14569, introduced by Representative Aswell, Louisiana, proposes to authorize an addition to the veterans' hospital at Alexandria, La. H. R. 14571, introduced by Representative Fuller, Arkansas, proposes the erection of a veterans' hospital in the northwestern part of Arkansas. H. R. 14686, introduced by Representative Christgau, Minnesota, proposes to authorize the use of the Mayo Clinic by the Veterans' Bureau as a diagnostic center and for the treatment of a limited number of the more serious ailments. H. R. 14690, introduced by Representative Edwards, Georgia, proposes to erect a marine hospital at Savannah, Ga. H. R. 14704, introduced by Representative Williamson, South Dakota, proposes to authorize an appropriation for construction at the Battle Mountain Sanitarium, National Soldiers' Home, Hot Springs, S. D. H. R. 14701, introduced by Representative Eaton, Colorado, proposes to authorize additions to the Fitzsimons General Hospital, Denver. H. R. 14682, introduced by Representative Schafer, Wisconsin, proposes to authorize an appropriation for construction at the northwestern branch, National Home for Disabled Volunteer Soldiers, Milwaukee. H. R. 14449, introduced by Representative Welsh, Pennsylvania, proposes to convert veterans' hospital numbered 49 in Philadelphia to a diagnostic center.

Plan for the Care of Crippled Children

At the first step in a plan to improve the condition of crippled children throughout Queensland, the Brisbane Rotary Club is preparing a register by circularizing the medical profession, churches, hospitals, police, and country women's associations. Each crippled child will be investigated as regards the nature of the disease, the prospect of improvement under treatment, and the nature of the treatment recommended. The last two aspects of the investigation will necessitate the examination of the children by orthopedic surgeons at central clinics. The inquiry is being conducted also into the resources available for the treatment of these children. The resources include orthopedic wards in hospitals, treatment by private practitioners, schools where vocational and ordinary education can be carried out in conjunction with orthopedic treatment, the placing of educated children, and hostel accommodation of those not amenable to improvement.

The first action of the crippled children's subcommittee of the Brisbane Rotary Club was to circularize the medical practitioners, acting on the principle established that no interference with private medical treatment shall take place. Under these conditions the scheme has the approval of the Queensland branch of the British Medical Association.

The commonest causes of crippling in Queensland are poliomyelitis and lead poisoning. Tuberculous bone lesions are rare.

Gift to Sydney University by Rockefeller Foundation

For the purpose of providing adequate laboratory facilities for the departments of medicine, surgery, pathology, bacteriology, and allied subjects of the medical curriculum, the Rockefeller Foundation of New York has contributed £100,000 to the Sydney University. Since the establishment of full-time chairs in medicine, surgery and bacteriology, made possible by the generosity of Mr. George Bosch of Sydney, the medical school of the university has been brought within the scope of the activities of the Rockefeller Foundation. This gift to the university was the outcome of the visit of Mr. Bosch and Professor Stump to America last January, when they explained in person the plans which the university had in view.

The Rockefeller Foundation has already exerted a beneficial influence in the medical educational field of Australia. Many fellowships have been awarded by the Foundation to graduates of Australian universities, and the Australian National Research Council has been subsidized in its anthropological researches.

The University of Sydney is becoming rapidly better equipped to develop its graduate teaching intensively and to provide better facilities for research in medical problems. It is the intention of the university to complete a new medical block close to the Royal Prince Alfred Hospital. The present medical building will continue to house the departments of anatomy, physiology, pharmacy and dentistry, and the new block will take in the department of medicine, surgery, pathology, bacteriology and other allied subjects, such as urology, which has been endowed by Dr. Gordon Craig. With these new developments and with the recently inaugurated School of Public Health and Tropical Medicine, the Medical School of Sydney University will continue to maintain its position in the forefront of the medical schools of the world.

Report on Cancer Treatment in Australia

Dr. Arthur Burrows, the commonwealth radium adviser, presented statistics to the recent cancer conference at Canberra showing that for the twelve months ended June 30, 1929, 2,500 cancer patients had been treated at various centers in Australia with the radium purchased by the commonwealth government. The majority of these cancer patients were inoperable; it is considered that 1,200 will have experienced alleviation of their symptoms. In Sydney, where the university senate acts as trustees of a fund of £100,000 subscribed publicly in New South Wales three years ago, the work has been carried out at the Royal Prince Alfred Hospital and St. Vincent's Hospital. At the Sydney Hospital there has been some delay in establishing a clinic owing to lack of accommodation. At the Royal Prince Alfred Hospital during the past twenty months more than 1,500 patients have attended the cancer clinic for diagnosis, consultation and treatment; more than 9,000 attendances of outpatients were recorded, apart from the indoor operative work. At St. Vincent's Hospital, which is about half the size of the Royal Prince Alfred Hospital and where the cancer clinic began work some months later, 350 patients have been similarly reviewed, involving about 3,000 outpatient's attendances apart, again, from the indoor surgical work. Treatment committees comprising physicians, surgeons, radiologists and pathologists selected from the honorary medical staffs of the hospitals meet regularly at the clinics in a reviewing capacity. By this method, a balanced opinion is obtained as to the method or combination of methods to be employed in each individual case.

The Hospital Problem of Melbourne

In recent years a political game of shuttlecock and battledore has been in progress in Victoria. It has involved the problem of the extension of hospital accommodations at Melbourne. The three main hospitals for the treatment of general patients—the Melbourne, St. Vincent's, and the Alfred—are well equipped and admirably managed, but they fall far short of meeting the demands for accommodations made upon them. The Melbourne Hospital is in the heart of the city, with street cars passing along three sides of it. It is convenient but noisy and restricted in area. Four years ago, Sir Stanley Argyle, a physician, was chief secretary of the state government then in office. In considering the question of hospital extension he adopted a grandiose scheme propounded by Professor Berry, head at that time of the medical school of the Melbourne University, for scrapping the present Melbourne Hospital and erecting a huge building on a large vacant space close to the university. The cost of this scheme was estimated at £800,000. Had it been permissible to sell the land on which the Melbourne Hospital now stands, all financial difficulties would have been overcome; but that could not be done. Sir Stanley Argyle did not seek legislative sanction for his scheme, and when the next government came into office it submitted an alternative plan for increasing each of the three metropolitan hospitals by the addition of another eighty beds each, and building a clinical hospital of a hundred beds in the university grounds for the training of medical students. The total cost of this proposal was estimated at £500,000. The board of charities approved of this plan, and the St. Vincent's and Alfred hospital authorities promptly accepted the government's offer and went ahead with the construction of the new wings. Before the Melbourne Hospital could do anything the government was again changed, and Sir Stanley Argyle, again becoming chief secretary, discarded the second plan and revived his original scheme. But again he failed to seek parliamentary sanction for the demolition of the Melbourne Hospital, and with the return to office of the former government the Melbourne Hospital management committee is again discussing the government's proposals for enlarging the hospital by building a new ward of eighty beds. The position is quite unsatisfactory and promises to remain so until the rival parties come to better understanding.

It is unfortunate that the miscarrying of Sir Stanley Argyle's plan for building a medical center near the university at Melbourne had weakened the request by the University of Melbourne

The Austrian System of Compulsory Health Insurance

The government regulation of sick relief for employees and workmen was established by the act of July 1, 1927, and supplementary legislation was passed in 1929. As a result, many of the smaller health insurance societies were merged into larger organizations. Since that time there have been four distinct types of health insurance societies (*krankenkassen*); *gebietskassen*, or regional societies (four); *betriebskassen*, or societies of industrial plants (twenty-one); *genossenschaftskassen*, or societies of certain trades (five), and *vereinskassen*, or group health insurance applied to previously existing organizations (twelve). The total insured membership of these four groups of societies, at the close of 1929, was 992,333, 48 per cent of which membership was in Vienna. The four regional societies comprised 76 per cent of the insured, whereas the *genossenschaftskassen* had only 5 per cent, and the *betriebskassen* only 3 per cent. There is still a tendency for the smaller societies to become absorbed by the larger societies. The figures do not give a clear picture of the actual conditions affecting the economic life of physicians in Austria, for in many societies also the families of society members are insured against sickness, and, in addition, there are the three large health insurance societies that take care of the government civil servants, the municipal civil servants and the government railway employees, respectively, in all of which the families are likewise fully insured. The total membership of these three societies is 600,000, of which 350,000 is in Vienna. Therefore, about 50 per cent of the population of Vienna is insured in some way against sickness and do not have to consult a physician in private practice; the remaining 50 per cent are either unemployed or, by reason of the economic stringency, are able to consult a physician in private practice only in dire emergency. The compensation received by the panel physicians of the health insurance societies is painfully uniform. The initial salary of the general panel practitioner is about 300 schillings, or $43, a month, with a 10 per cent increase every three years, up to a maximum of 550 schillings, or about $80. Specialists receive an initial salary of 400 schillings ($58), with increases up to 700 schillings, or $100. For the treatment of members of the family of the insured an additional sum is allowed, depending on the number of such members that consult the physician. As a rule, the serving of more than one health insurance society by a physician is discouraged, in order that the oncoming generation of physicians may obtain at least enough compensation to exist. The income of a practicing physician who is almost entirely dependent on the health insurance society will average from 800 to 1,000 schillings ($120-$150). It should be mentioned, however, that nearly all panel physicians with fixed compensation are entitled to old age insurance with a pension that ranges from 35 to 100 per cent of the last salary received, depending on the length of service. The pension system constitutes an inducement to many physicians to seek engagement as a panel physician, just as many persons desire a position in the government service by reason of the assurance of adequate care in old age.

Securing Directors for Vacancies in Vienna Clinics

Through the resignation of Professors Wenckebach and Ortner as directors of the two clinics for internal diseases, a difficult situation has been created. For the position of Wenckebach, the first to receive consideration were Professors Assmann of Leipzig and Vollhard in Frankfort. However, an agreement could not be reached with either one of them. Tentative offers were then made to Morawitz in Leipzig and Schittenhelm in Kiel. To the great surprise of academic circles, both men rejected the offers, probably on account of the reactionary attitude of the majority in the collegium of professors. On the other hand, Prof. Dr. Schmidt of the German University of Prague has consented to take over the direction of this clinic in Vienna. Furthermore, Professor Tagić, a clinician of Vienna, is being considered as successor to Professor Ortner, who is at present suffering from bulbar paralysis. A strong group, however, would like to secure Prof. Dr. Eppinger, who until recently was an instructor at the University of Freiburg but who has been called to Cologne. The decision will soon be reached. For the position of director of the first surgical clinic, which became vacant through the retirement of Professor Hochenegg on attaining his seventieth year, Professor Clairmont, who is now in charge of the surgical clinic in Zurich (Switzerland), has been chosen. The second clinic for surgery in Vienna (the Eiselsberg clinic) also will soon be in need of a director, who will likewise be difficult to find, as this post requires a man of international prominence, and such men will likely make demands that Vienna will be unable to meet.

Indications for Treatment in Appendicitis

In the seminar for practicing physicians, which is held in Vienna every week by the collegium of doctors of medicine, Privatdozent Dr. Demmer presented a paper on the topic "When Should an Operation Be Performed in Acute Appendicitis and When Should a Conservative Attitude Be Taken?" The classic symptoms required by strict indications are often wanting. Of 450 operations that the author performed for acute appendicitis, 160, or 35 per cent, came to operation too late, with the result that 72 cases proved fatal; 69 cases became perforated; in 89 cases drainage was necessary; 55 cases had nearly reached the forty-eight hour limit, and 99 patients were admitted after the forty-eight hour period. Not even a third of all cases showed before the operation the classic symptom complex. Often a disorder of the adnexa, of the gallbladder, duodenal ulcer or acute gastro-enteritis is suspected. Neither an ice bag nor opium nor calomel and castor oil should be prescribed. The last mentioned remedy has often been found in the abdomen after an "explosive" perforation. Dr. Demmer recommends in every inflammatory peritoneal process that the patient be removed to a surgical department before the lapse of forty hours since the onset of the attack, because a later removal often causes perforation. It is important that the shifting of the inflammation to the peritoneum is recognized in time and is correctly understood. The following management is recommended: differential axillary and rectal temperature determination, a small enema of 1 pint in the dorsal position, a steam pack applied to the abdomen with a thermophore, in the dorsal position; no food other than tea. The case is urgent if, in spite of the aforedescribed treatment, even a single symptom becomes more prominent within three to six hours and the enemas are unsuccessful, or the pulse and temperature show an upward trend, or if the difference between the axillary and the rectal temperatures is more than 1.5 degrees centigrade and is increasing or is constantly more than 1 degree. The latter cases are always to be regarded as grave. The greatest differentiation between the axillary and the rectal temperature hitherto observed was 2.2 degrees. The rapidity of the increase in temperature is an important point. If the symptoms just described are not present, a conservative attitude may be maintained, provided all symptoms are most carefully controlled.

Marriages

Theodore A. Dykhuizen, Indianapolis, to Miss Zella Gwendolyn Tuttle of Greencastle, Ind., in Cincinnati, October 11.

George J. Van Besien, Dixon, Iowa, to Miss Ella Genevieve Minihan of Davenport, October 16.

Charles Murray Gratz, New York, to Miss Bernice Delemar West, December 9.

Howard Harpst to Miss Helen Louise Jones, both of Toledo, Ohio, October 10.

Luther S. Hirt to Mrs. Minnie Laverty, both of Brazil, Ind., October 5.

Deaths

Robert Martin Culler ⊕ Lieut.-Colonel, U. S. Army, retired, Oxford, Md.; Jefferson Medical College of Philadelphia, 1901; member of the American College of Surgeons; entered the army as assistant surgeon in 1904; rose through the various grades to that of lieutenant colonel; served during the World War; retired in 1922 for disability in line of duty; aged 53; died, August 4.

Henry Thomas Machell, Toronto, Ont., Canada; University of Toronto Faculty of Medicine, 1873; L.R.C.S., Edinburgh, and L.R.C.P., Edinburgh, Scotland, 1875; emeritus professor of obstetrics and pediatrics, University of Toronto Faculty of Medicine; for many years on the staffs of St. John's Hospital and the Hospital for Sick Children; aged 80; died, November 9.

Ernest Ellsworth Smith ⊕ New York; Bellevue Hospital Medical College, New York, 1898; professor of physiology and biological chemistry, Fordham University School of Medicine, 1906-1911; secretary of the Medical Society of Queens County; aged 62; died, December 5, of heart disease.

John Charles Lawlor ⊕ Dover, N. H.; Harvard University Medical School, Boston, 1915; member of the Associated Anesthetists of the United States and Canada and the American College of Surgeons; served during the World War; aged 42; died, December 9, of pneumonia.

Abe Hayman, Brooklyn; Medical Department of the University of the City of New York, 1890; member of the Medical Society of the State of New York; for many years on the staff of the Beth Moses Hospital and the Jewish Hospital; aged 61; died, November 30.

Charles Bowman Bacon, Brooklyn; University of Buffalo School of Medicine, 1897; member of the Medical Society of the State of New York; superintendent of the Kings County Hospital; aged 60; died suddenly, December 10, of heart disease.

Maritt J. Rand ⊕ Ely, Nev.; University of Minnesota College of Homeopathic Medicine and Surgery, Minneapolis, 1907; member of the Associated Anesthetists of the United States and Canada; aged 52; died, November 5, of arteriosclerosis.

William Leland Mitchell ⊕ Budapest, Hungary; Washington University School of Medicine, St. Louis, 1918; field director of the Rockefeller Foundation, International Health Division; aged 37; died, November 20, of arteriosclerosis.

John Ralph Commorato ⊕ Jersey City, N. J.; Columbia University College of Physicians and Surgeons, New York, 1908; served during the World War; aged 44; died, November 29, in St. Francis Hospital, of septic poisoning.

Baxter Morgan Haynes, Spartanburg, S. C.; North Carolina Medical College, Charlotte, 1905; member of the state board of medical examiners; at one time county health officer; aged 51; died, November 18, of a self inflicted bullet wound.

Roy Cleveland Long, Johnson City, Tenn.; University of Tennessee College of Medicine, Memphis, 1912; on the staff of the Mountain Branch of the National Home for Disabled Volunteer Soldiers; aged 49; died, October 1.

Charles Edward Lovell, Whitman, Mass.; Dartmouth Medical School, Hanover, N. H., 1885; member of the Massachusetts Medical Society; member of the board of health of Whitman; aged 69; died, October 31.

John Stanley Boyer, Detroit; University of Michigan Medical School, Ann Arbor, 1924; member of the Michigan State Medical Association; aged 33; died, November 21, in the Providence Hospital, of pneumonia.

James Joseph Buckley ⊕ Dover, N. H.; Dartmouth Medical School, Hanover, 1900; on the staffs of the Hayes Hospital and the Wentworth Hospital; aged 53; died, November 4, of carcinoma of the bladder.

Edson Haskell Lutze, Brooklyn; New York Homeopathic Medical College and Flower Hospital, 1910; on the staff of the Prospect Heights Hospital; aged 57; died, December 7, of cerebral hemorrhage.

Morris Tipton, Columbus, Ohio; Medical College of Ohio, Cincinnati, 1883; formerly probate judge; on the staff of the State Hospital; aged 70; died, November 10, in Gallipolis, of cerebral hemorrhage.

William Sinclair McClinton, Midland, Ont., Canada; University of Toronto Faculty of Medicine, 1919; served during the World War; aged 35; was accidentally drowned, October 31, in Georgian Bay.

Marshall Collier McIntire, Farmer City, Ill.; Hahnemann Medical College and Hospital, Chicago, 1879; aged 72; died, November 20, of arteriosclerosis and obliterative endarteritis.

Robert Selmo Barton, New Philadelphia, Ohio; Columbus Medical College, 1884; member of the Ohio State Medical Association; aged 70; died, November 15, of angina pectoris.

Gustave Adolphus Petersdorf, Indianapolis; Medical College of Indiana, Indianapolis, 1898; aged 54; died, December 1, of acute dilatation of the heart and chronic myocarditis.

Edward G. Hedrick, Loraine, Ill.; College of Physicians and Surgeons, Keokuk, Iowa, 1891; aged 66; died, November 24, in the Blessing Hospital, Quincy, of cerebral hemorrhage.

Bayliss McCuan Little ⊕ Clearfield, Iowa; Vanderbilt University School of Medicine, Nashville, Tenn., 1914; aged 40; died, October 27, of encephalitis and pneumonia.

Fred Schneider ⊕ New London, Wis.; Grossherzogliche Hessische Ludwigs Universität, Giessen, Hesse, Germany, 1876; aged 80; died, November 24, of bronchopneumonia.

Joseph D. Parr, Marietta, Ohio; Pulte Medical College, Homeopathic, Cincinnati, 1890; aged 70; died, October 30, in a hospital, at Detroit, of coronary thrombosis.

Eugene Chambers Kensinger, Athens, Tenn.; Memphis (Tenn.) Hospital Medical College, 1913; aged 44; died, November 27, following an operation for appendicitis.

Edwin Butler Shaw ⊕ Las Vegas, N. M.; Long Island College Hospital, Brooklyn, 1882; on the staff of the Carpenter Memorial Hospital; aged 72; died, July 13.

Harold Hartley Cauble, Kannapolis, N. C.; North Carolina Medical College, Charlotte, 1909; aged 46; died, November 20, in Salisbury, of heart disease.

Charles A. Stulik, Sr. ⊕ Chicago; Rush Medical College, Chicago, 1894; aged 70; died, October 6, of pulmonary embolism and carcinoma of the prostate.

William H. Ward ⊕ Plymouth, N. C.; University of Maryland School of Medicine, Baltimore, 1881; aged 73; died, November 9, of angina pectoris.

Nicholas F. Kelly Ake, Du Bois, Pa.; Medico-Chirurgical College of Philadelphia, 1897; aged 57; died, November 29, of bronchial asthma and influenza.

James Sidney Ames ⊕ Babylon, N. Y.; Columbia University College of Physicians and Surgeons, New York, 1909; aged 48; died in November.

John E. Harner, Ephrata, Pa.; Homeopathic Hospital College, Cleveland, 1882; aged 78; died, November 18, in New Holland, of myocarditis.

Conley Mahlon Cowan ⊕ Bristol, Tenn.; Tennessee Medical College, Knoxville, 1902; aged 52; died, October 30, of cerebral hemorrhage.

Fred A. Cogswell, Leona, Kan.; State University of Iowa College of Medicine, Iowa City, 1889; aged 67; died, in October, in Wetmore.

Henry J. Hahn, Jr., Baltimore; University of Maryland School of Medicine, Baltimore, 1899; died suddenly, December 5, of heart disease.

William Harvey Zieber, Palo Alto, Calif.; College of Physicians and Surgeons, Keokuk, Iowa, 1890; aged 68; died, November 19.

Thomas Rankin Wilson, Montreal, Que., Canada; McGill University Faculty of Medicine, Montreal, 1904; aged 65; died, August 28.

Henry A. Simpson, Afton, Tenn.; Lincoln Memorial University Medical Department, 1911; aged 69; died, October 16.

Peter R. Bacot, Varnado, La.; University of Louisville (Ky) School of Medicine, 1893; aged 65; died, November 14.

Robert Scrimgeour ⊕ Brooklyn; Long Island College Hospital, Brooklyn, 1881; aged 88; died, November 17.

Leonidas Gardner Brock, Lytle, Ohio; Medical College of Ohio, Cincinnati, 1881; aged 80; died, November 14.

William Thomas Amyx, Lexington, Ky.; Louisville (Ky.) Medical College, 1894; aged 63; died, November 15.

Horace W. Elder, Bloomington, Ill.; Barnes Medical College, St. Louis, 1893; aged 70; died, in October.

Samuel W. Stone, Tazewell, Tenn. (licensed, Tennessee, 1889); aged 85; died, November 26.

Henry H. Cook, Detroit; Detroit College of Medicine, 1897; aged 55; died, December 1.

John A. Barnes, Louise, Miss. (licensed, Mississippi, 1882); aged 70; died, November 20.

Correspondence

THE DISCOVERY OF THE TRICHINA

To the Editor:—Recently (October 11) the *British Medical Journal* commented on the confusion concerning the historical record of the discovery of trichina. Even the recent edition of Osler's textbook failed, according to the editorial comment, to state correctly the facts regarding the original discovery of this important human parasite. The comment was entirely just and all the more inexplicable since numerous present-day textbooks on parasitology in English state the facts correctly.

Inadvertently the editorial writer himself slipped. The last sentence in the editorial reads:

> The life-history of the trichina was fully worked out by Herbst, Virchow, Zenker and Kühne, who completed a discovery made by a medical student of twenty-one years.

This statement omits entirely any reference to the most significant discovery among those of the many investigators who contributed to working out the life history. It was the demonstration of a similar encysted stage in the pig. For this the distinguished American physician and investigator Dr. Joseph Leidy of Philadelphia was responsible. The older authors overlooked the leading part he played in laying the foundations of parasitology, perhaps by virtue of his outstanding contributions in other fields. This oversight was adequately corrected by numerous addresses delivered on the occasion of the Leidy centenary in Philadelphia during September, 1923.

Leidy's part in the elucidation of the life history of trichina was one of his most significant contributions to research, giving the key to unlock the story of the life cycle of this parasite and at the same time furnishing the foundation for a simple and effective method for the prevention of the disease.

In 1846 Leidy recorded the discovery of minute encysted worms in the hog. He wrote that he "could perceive no distinction between it and specimens of *Trichina spiralis* which he had met with in several human subjects." This record is a striking illustration of the keenness with which an apparently trivial item acquired significance in his eyes; and if this interpretation of the relation between trichina in the hog and the occurrence of this parasite in man had been immediately accepted it would have hastened the general recognition of the responsibility of the pig for the transmission of the disease by at least a score of years.

The record was copied in England but the systematic parasitologist Diesing in Germany listed Leidy's find under the name *Trichina affinis* as a new species, throwing a mess of superficially studied and imperfectly described larval forms from a dozen hosts into the same species.

In 1896 Virchow told Leidy's nephew personally that he had had a lengthy correspondence with Leidy in 1849 and 1850 and that this correspondence on Leidy's discovery suggested to Leuckart and to himself the experiments which ultimately settled the life cycle of the parasite. In the meantime, Leidy's discovery as reported by Diesing under the new but erroneous designation was utilized to support false views of others that the encysted form in the pig was the larval stage of the adult trichuris in man.

Leidy did not lose interest in this problem, for in 1859 he exhibited to the Philadelphia Academy trichina in infested muscles from the human subject and stated that he had often met the parasite. In the following year he reported Leuckart's experiments and in 1866 in response to a question from a member of the academy stated simply but clearly that he was the first to discover the parasite in the hog. He related more fully the circumstances attending the discovery and in conclusion emphasized the freedom from danger of infection if meats were thoroughly cooked, "for he had satisfied himself by experiment that entozoa are destroyed when submitted to the temperature of boiling water."

Leidy was strongly averse to controversy and when urged by his friends to proclaim his part in the discovery and its importance he quietly replied, "The important thing is that the discovery or fact should be made known. It is of little consequence who made it." He preferred freedom from "disturbance of that peace of mind" which interfered so seriously with his researches.

American science owes much in a variety of fields to Leidy's devotion to real research and American medicine may well be proud of one of its members in a former generation who contributed so largely to the foundations of scientific research not only in parasitology but in a half a dozen other lines of investigation. In the particular case under discussion, his discovery was certainly fundamental and should be generally recognized.

Urbana, Ill.

AGRANULOCYTIC ANGINA

To the Editor:—The editorial writer who reviewed the subject of agranulocytic angina in The Journal, November 8, made one mistake. I believe the first case on record to be one that I reported in *American Medicine* (**3**:649 [April 19] 1902). As this case was studied pathologically and bacteriologically, it is certainly worth recording in connection with the history of this trouble.

To meet the question raised as to the distinction between this disease and aleukemic leukemia, I am going to send you shortly a review of both of these conditions as I have come across them recently.

Philip King Brown, M.D., San Francisco.

[Note.—Examination of the article by Dr. Brown, the title of which is "A Fatal Case of Acute Primary Infectious Pharyngitis, with Extreme Leukopenia," reveals that it does concern a case that now undoubtedly would be classed under agranulocytic angina. The case appears to be the first of its kind on record according to the information now at hand. Thanks are due him for calling attention to the failure by previous writers on agranulocytic angina to include his case in their discussions.—Ed.]

INTRODUCTION OF WORD "ANAPHYLAXIS"

To the Editor:—In an editorial in The Journal, October 18, discussing the establishment of the National Institute of Health, there is reference to the contributions that the Hygienic Laboratory of the Public Health Service (which forms the nucleus for the new expansion) has made to the betterment of human health. In the course of this recital, it is stated: "Early studies of anaphylaxis, a word which, by the way, was coined at the Hygienic Laboratory, brought the phenomenon of hypersusceptibility to the attention of research workers throughout the world." I had assumed that the term anaphylaxis was coined by Prof. Charles Richet of Paris, who was awarded one of the earliest Nobel prizes in medicine for this contribution. Am I in error?

M.D., Connecticut.

[Comment.—Our correspondent is correct, and the statement in The Journal was inadvertently erroneous. In "The Principles of Immunology" (Philadelphia, J. B. Lippincott Company, 1921), Karsner and Ecker state (p. 209) in reference to anaphylaxis: "Experimentally similar phenomena had been noted in the course of other studies as far back as Magendie in 1839, but it remained for Richet and Portier in 1902 to point out the fact that an animal may be rendered hypersusceptible to a poison by a previous injection of a small dose. . . . Because the phenomenon indicates a condition the opposite of prophylaxis they named it anaphylaxis." Again, in Jordan, E. O., and Falk, I. S.: The Newer Knowledge of Bacteriology and Immunology (University of Chicago Press, 1928) it is stated (page 969):

"The basic statement of the nature of anaphylaxis is given simply by the discoverer Richet (Richet, C.: L'Anaphylaxie, Paris, Alcan, 1923). . . . The term 'anaphylaxis' (ana, 'against'; phylax, 'guard') coined as a result of physiologic experiments, came into general use when the more strictly immunologic work of Arthus, Otto and Rosenau and Anderson gave the key to the mysterious ill effects that sometimes follow the use of horse serum in the treatment of diphtheria." Furthermore, in their Harvey Lecture, delivered, Dec. 5, 1908, Anderson and Rosenau (The Harvey Lectures, 1908-1909, Philadelphia, J. B. Lippincott Company, 1910), who were at that time associated with the Hygienic Laboratory, stated (page 117): "The word 'anaphylaxis' was introduced by Richet."—Ed.]

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

SILICOSIS AND PNEUMONOCONIOSIS

To the Editor:—In Queries and Minor Notes (The Journal, August 30, p. 684) you state that "the silicate would ultimately load the lungs." The expression "load the lungs" would seem to imply the production of well marked pneumonoconiosis. This is produced, as I understand it, almost exclusively by free silica. With the exception perhaps of asbestos fiber, dust in general never loads the lungs and, in fact, causes relatively little damage of a serious nature. The work of Landis in Philadelphia substantiates this. Accordingly, I am wondering whether you have any basis for your statement that silicates are injurious.

Henry F. Stoll, M.D., Hartford, Conn.

Answer.—Silicates, as well as free silica, are definite sources of pneumonoconiosis. At an earlier time it was maintained that the hardness of the siliceous material, together with the acidulate qualities of the particles, played a considerable part in the causation of silicosis. This concept led to greater significance being attached to hard forms of silica rock, such as ganister and flint. At present, it seems necessary to abandon these theories and to attach greater significance to the chemical properties of siliceous materials as the source of harm.

Silicates, as well as free silica, are the sources of pneumonoconiotic diseases, although there may be some variation in the severity of the condition and in the length of time required for its production. In addition, some variation may exist in the pathologic condition produced. For example, asbestos, which is magnesium silicate, produces changes in the lungs somewhat unlike silicosis from granite. Roentgenologists, highly skilled in this particular field, are able to sort out, with reasonable accuracy, films of pneumonoconiotic lungs from asbestos and from free silica.

In this country the principal work on silicosis is that being carried out in The Tri-State Lead and Zinc Ore Districts of Missouri, Oklahoma and Kansas. This research work is jointly maintained by the United States Public Health Service and the Metropolitan Life Insurance Company. Reference is made to either of these agencies for more extensive information as to silicates as producers of pneumonoconiosis.

While it is granted that much remains to be proved in connection with silicosis and other dusty lung diseases, it does appear well established that silicates are sources of pathologic changes in the lungs, at least akin to the condition that is now termed "silicosis."

TOXICITY OF "CELLOSOLVE"

To the Editor:—A textile concern with which I am connected is using as a solvent for dyes a preparation known to the trade as "cellosolve." which chemically is ethylene glycol monoethyl ether. The boiling point is 134.8 C. I would appreciate any information you could give me concerning possible toxic effects, local or systemic, on workmen handling this preparation.

A. S. Jones, M.D., Shamokin, Pa

Answer.—The toxicity of "cellosolve" was discussed in *Public Health Reports*, June 27. The investigative work was largely limited to guinea-pigs, although two of the investigators breathed 0.6 per cent of cellosolve vapors for a few seconds only and reported some irritation to the eyes. The conclusions of the authors with reference to animals may be thus summarized:

1. The symptoms exhibited after from eighteen to twenty-four hours' exposure to air saturated with cellosolve vapor (0.6 per cent by volume) were inactivity, weakness, dyspnea and death. Exposure to 0.6 per cent for twenty-four hours caused death at the end of the exposure; 0.3 per cent for twenty-four hours caused death in twenty-four hours following exposure, and exposure to 0.6 per cent for ten hours, 0.3 and 0.1 for eighteen hours, caused occasional death in from one to eight days following exposure. Exposure to 0.6 per cent for one hour, 0.3 for four hours and 0.05 for fourteen hours did not cause any apparent harm.
2. The principal gross pathologic appearances were congestion and edema of the lungs; distention of the stomach, with numerous reddish-brown petechiae scattered over the mucous membrane, and congestion of the kidney. The contents of the stomach were also discolored reddish brown. All these occurred in the animals that died during or soon after exposure. Congestion and edema were the principal conditions in the animals that died twenty-four hours following exposure, and bronchopneumonia in the animals that died three days following.
3. Because of the comparatively low vapor pressure of cellosolve, it is not possible to create atmospheres at ordinary room temperatures that will produce serious acute poisoning in an hour.
4. Air saturated with cellosolve vapor at room temperatures produces a disagreeable odor and produces moderate eye irritation. If these properties are heeded as a warning of the occurrence of a potentially dangerous atmosphere, it is believed that acute poisoning will not occur."

The inference is that ethylene glycol monoethyl ether is definitely toxic for guinea-pigs and is presumably toxic for human beings, but that the physical conditions attending its use in industry do not readily lend themselves to circumstances likely to produce severe intoxication.

EPIGASTRIC PAIN

To the Editor:—An otherwise healthy man, aged 28, suffers from recurrent attacks of severe epigastric pain, accompanied by nausea and vomiting. The patient has a subnormal temperature during these attacks, which requires the use of morphine for alleviation. The attacks come on quite often while the patient is sleeping and last for several hours. There is some tenderness and rigidity over the epigastrium. A roentgen study, done about three years ago, did not reveal any pathologic changes. Last year a gastro-intestinal series revealed the presence of chronic appendicitis. Exploratory laparotomy was done and no other pathologic change was found. The appendix was removed. The patient still suffers from the attacks, although not so frequently. I have hazarded an impression that the pain is that of a gastralgia of anaphylactic causation. What is your opinion? Kindly omit name.

M.D., Michigan.

Answer.—A diaphragmatic hernia should be considered as a possibility. Such a herniation is more prone to occur in the recumbent position, and sufferers from such a hernia may prefer to sleep propped up in bed to prevent the attacks. It could be present and still not show in one or two roentgen examinations. Similar pain was experienced by a patient with sarcoma of the retroperitoneal glands, a growth so small that it could not be palpated. The history is of too long a duration for a tumor of the liver. Other unusual herniations of the upper part of the abdomen should be considered. The possibility of a reflex from pathologic changes above the diaphragm should be considered, as an adhesive pericarditis or a mediastinal disorder.

OCULAR MUSCLE IMBALANCE

To the Editor:—A patient, aged 50, is troubled with paretic hyperphoria affecting the right superior oblique muscle. It is evidently not of central origin but is most likely due to some structural anomaly of the muscle itself or is traumatic. Close application, such as reading or writing, causes a reflex disturbance of the heart manifested in a distressing heart consciousness and by a sense of oppression. This has lately led to frequent attacks of extrasystole which always follow prolonged close application, even with the proper correction for astigmatism and presbyopia and with the use of either both eyes or one eye. Prisms only make the matter worse. Two authorities whom I have consulted recommend covering the affected eye. In this case there happens to be a small retinal central scotoma, the result of having viewed a sun eclipse, which interferes with the procedure that has been advised. Is there an objection against the use of the affected eye alone instead of the sound eye in hyperphoria? If not, can you suggest a probable cause for the persistence of the cardiac strain following such use for close work. Please omit name.

M.D., New Jersey.

Answer.—There can be absolutely no objection to the use of an eye with a paralyzed muscle, provided the motion of that eye is not so limited as to interfere. There is a definite but not well understood relationship between the eye and the cardiac mechanism, of which the best known manifestation is the oculocardiac reflex. This is supposed to function by way of the sympathetics and the vagus, and it is easy to conceive of a similar reflex disturbance due to ocular muscle imbalance.

CONGENITAL HEMANGIOMA

To the Editor:—Will you please inform me what can be done for an infant, aged 3 months, who has a congenital hemangioma of the lip with similar angiomatous changes on the gums and even on the tongue. Can you please advise me to whom I can refer this patient for treatment in New York.

A. J. Reich, M.D., New York.

Answer.—The treatment of such extensive hemangiomas is rarely so satisfactory as it is in the smaller ones, which may be excised. Many times the white scar following the use of radium is fully as objectionable as the red or port wine mark. If one succeeds in destroying the blood vessels it may be possible by extensive plastic surgery to attain a passable cosmetic result. At times the condition is progressive and continues to involve more of the normal tissue. The increase in the size and number of the veins may cause an enlargement of the lip and cheek, giving them a hypertrophic appearance.

One may consider surgery or the introduction of radium seeds into some parts of the tumor with topical application of radium to the skin. Some excellent results in selected cases have been attained by the hypodermic injection of boiling water. There is, however, some danger of causing a slough.

HEKTOEN PHENOMENON

To the Editor:—Not long ago I was called to see a patient with pernicious vomiting and found her with a temperature of 103 F., heart rate 116 and a rough systolic murmur. Bromides and carbohydrates helped the morning nausea to some extent but less than usual, and the temperature was revealed as of septic type varying from 99.5 F. to 104 F. She was hospitalized and then I found that on two occasions she had a pure blood culture of streptococci and also a positive Widal reaction 1:60, although she had never had typhoid and had never had typhoid vaccine. I am able to explain this positive Widal only by suggesting that it represents what The Journal has recently described as the Hektoen phenomenon. As I had never heard of the Hektoen phenomenon, I would welcome your opinion. The patient, by the way, has recovered, is doing her housework and is going on with her pregnancy, which will be at term, Jan. 7, 1931. She still has her heart murmur, is free from fever, and has a blood pressure of 138/78, pulse 92 (allowance must be made for nervousness in this case), slight puffiness of the ankles in the evening and lately a dull soreness but no pain in the left arm. Do you think she could deliver normally (fifth child)? The passages are fully competent and she always has an easy and short delivery. Can you suggest any precautions that could be taken?

M.D., N. Y.

Answer.—When antigens, e. g., infectious agents, are introduced into the animal body in a so-called sensitized or allergic state, whether due to previous natural infection or to experimental procedures, there may exist a widened range of new antibody production, which may include production of antibodies concerned in previous infections or immunizations. It is possible that the patient may have had a typhoid infection that was not recognized and that the agglutination at 1:60 of typhoid bacilli was due primarily to that infection. As the agglutinin titer of the serum before the illness is not known, it cannot be known whether the agglutination was the result of a reawakening of agglutinin production by the stimulus of the infection. There is no apparent reason why, with careful ordinary precautions, the patient should not go on to term with normal termination.

SEXUAL EXHAUSTION AFTER EXCESS

To the Editor:—Will you kindly give me the following information concerning cases of sexual exhaustion after juvenile excess in young males? 1. Is thyroid extract of added help when combined with anterior pituitary lobe extracts? 2. Would you expect a child of such a father to be normal? 3. What would you suggest as a fitting length of time for treatment before discharging a patient as definitely incurable? 4. Would prolonged hypodermic injection of anterior pituitary lobe extract have a deleterious effect on the patient? 5. Would complete abstinence from sexual intercouse help such patients? 6. Is there a definite possibility of restoring the sexual power in such cases when a specimen, though small, contains actively motile spermatozoa? 7. What changes should be expected in such patients if they do not respond to treatment? 8. What literature treats this subject satisfactorily. - Please omit name and address.

M.D., New York.

Answer.—1. There is no evidence available to support the belief that thyroid extract enhances the stimulating effect of anterior pituitary lobe extracts.

2. There is no reason to expect any abnormality in a prospective child.

3. The period of treatment for any kind of impotence is always a prolonged one and no special term for the abandonment of treatment may be fixed.

4. As far as it is known, prolonged injections of anterior pituitary lobe extract do not show deleterious effects in male individuals.

5. Complete abstinence is imperative during treatment.

6. The presence of active spermatozoa is a favorable symptom.

7. Failure of therapeutic success does not produce any general constitutional symptoms.

8. The subject is thoroughly covered in Max Hühner's Practical Treatise on Disorders of the Sexual Function in the Male and Female, ed. 3, Philadelphia, F. A. Davis Company, 1929.

Wisconsin: Madison, Jan. 13-15, 1931. Sec., Dr. R. E. Flynn, 315 State Bank Bldg., La Crosse, Wis.

Wyoming: Cheyenne, Feb. 2, 1931. Sec., Dr. W. H. Hassed. Capitol Bldg., Cheyenne, Wyo.

South Carolina June Examination

Dr. A. Earl Boozer, secretary of the Board of Medical Examiners of South Carolina, reports the written examination held at Columbia, June 24-26, 1930. The examination covered 17 subjects and included 75 questions. An average of 75 per cent was required to pass. Thirty-five candidates were examined and passed. The following colleges were represented:

College	PASSED	Year Grad.	Per Cent
Medical College of the State of South Carolina		(1909)	77.4,
(1930) 80.6, 81.1, 82.5, 82.5, 83.4, 83.9, 84.9, 85, 85.4, 85.6, 85.9, 86.2, 86.6, 86.6, 86.9, 87, 87.4, 87.6, 88.2, 88.5, 88.6, 89, 89, 89.4, 89.7, 89.9, 90.2, 90.4, 91, 91.5, 92.			
Vanderbilt University School of Medicine		(1930)	92.1
Medical College of Virginia		(1930)	88.6
Osteopaths			81.4

Dr. Boozer also reports 4 physicians licensed through reciprocity with other states at the same meeting. The following colleges were represented:

College	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
Emory University School of Medicine		(1925)	Georgia
University of Georgia Medical Department		(1927) (1928)	Georgia
University of Maryland School of Medicine		(1911)	Georgia

Hawaii July Examination

Dr. James A. Morgan, secretary of the Board of Medical Examiners of Hawaii, reports the written examination held at Honolulu, July 14-17, 1930. The examination covered 10 subjects and included 55 questions. An average of 75 per cent was required to pass. Three candidates were examined and passed. The following colleges were represented:

College	PASSED	Year Grad.	Per Cent
Rush Medical College		(1930)	85.1
Boston University School of Medicine		(1929)	87.7
Western Reserve University School of Medicine		(1918)	86.9

Book Notices

Handbook of Pediatric Procedures. By Francis Scott Smyth, M.A., M.D., Pediatrician-in-Chief, University of California Hospital, and Edith I. M. Irvine-Jones, M.B., Ch.B., Assistant Physician, St. Louis Children's Hospital. Cloth. Price, $2.50. Pp. 212. New York: Macmillan Company, 1930.

This small but concise volume contains brief descriptions in outline and didactic form of the various methods emphasized in routine pediatric procedures. The authors have divided the book into two main sections, the first dealing with diagnosis and the second with therapy. After a detailed scheme for a complete history and physical examination is given, the common laboratory examinations of the blood, stool and urine are detailed. Then follow outline enumerations of the more special laboratory procedures, references being included to the original descriptions of the tests in the literature. The second part of the volume, dealing with therapy, considers first dietetic procedures. In measuring the quantities of various substances used in infant formulas, the metric system is followed. In the diets for children aged 1 year and over which follow, ounces and kilograms are quite freely mixed. In a practical book of this type it would be better to accept and employ throughout the more commonly used avoirdupois system. Under biologic therapy the authors state that the final reading in the Schick test should be made after forty-eight hours. It is generally accepted that this final reading be made ninety-six hours after the test was performed. The methods given for smallpox vaccination are the multiple puncture and the intradermal methods. No mention is made of the scratch method, which is undoubtedly by usage and general acceptance the standard method for vaccination. Under drug therapy, a table for dosage of the most common drugs at various ages is given. The dosage for codeine, one-eighth grain at 6 months; from one-fourth to one-half grain at 2 to 5 years, is dangerously high. The same is true of the dosage for thyroid, 1 grain at 6 months and from 2 to 4 grains at 3 to 5 years. In describing the therapy of acute and subacute pyelitis, the authors recommend hexamethylenamine, 4 grains three times daily, for a child of 5 years. This dosage is high and might produce hematuria. This book contains a vast amount of valuable material in concise form and should prove a handy reference for both the student and the practitioner.

Untersuchungen über das periphere Nervensystem. Serie A. Heft 1: Die Injektion des Nervensystems. Arbeiten aus der dritten Abteilung des anatomischen Institutes der Kaiserlichen Universitat Kyoto. Herausgegeben von Prof. Dr. Seigo Funaoka, Vorstand der Abteilung. Paper. Various pagination. Kyoto: Anatomical Institute of Kyoto Imperial University, 1930.

Funaoka and his collaborators successfully inject peripheral nerves with fluids which are not soluble in water (benzene, chloroform, toluene, aniline, liquid petrolatum, olive oil), and which can be colored. Funaoka prefers a colored oil, ultramarine, dissolved in decalene, benzene or a similar chemical (carbohydrate) substance. Injected into a peripheral nerve, sciatic or peroneal, for instance, with an ordinary glass syringe, the fluids spread easily through the length of the nerve, from which they extend into the central nervous system. On microscopic examination a dyed mass is found not only in the epineurium and perineurium—the connective tissue membranes of the peripheral nerves—but also in the subarachnoid and subdural spaces of the brain. On intradural injection of lampblack suspended in machine oil, coal particles are found within the cerebral ventricles and at the base of the brain. When the sediments of lampblack are especially abundant around the medulla oblongata, an internal hydrocephalus is inevitably produced. By injecting a 0.2 per cent solution of cocaine or procaine hydrochloride, also suspended in machine oil, it was possible to obtain analgesia of the opposite extremity, while injection of the nervus mentalis resulted in an anesthesia, of forty minutes' duration, of the whole area innervated by the trigeminal nerve. Other experiments convinced the Japanese investigators that the entire central nervous system may be injected from the peripheral nerves. The nerves themselves when injected with colored fluids could be traced to their finest ramifications and, when such fluids as methyliodide and ethyliodide were used, it was possible to obtain roentgenograms of the injected nerve. It was also possible to prove that caffeine, strychnine and picrotoxin injected into the peripheral nerves exert a direct physiologic action on the central nervous system, similar to the one exerted by the drugs when injected intravenously or subcutaneously. These few instances may give an idea of the originality and importance of the work done by Funaoka and his collaborators. One may say that it solved definitely, among other problems, the one pertaining to a communication between the cerebrospinal spaces—subarachnoid and subdural—and the perineural tissue spaces, a view long ago advocated by Key and Retzius. Also the experiments with the production of hydrocephalus are of great value, for they prove that the blocking of the area around the medulla is a necessary factor in the causation of this condition. The issue consists of twelve contributions with excellent photographs, one beautiful colored picture and a rich bibliography.

J. George Adami, Vice-Chancellor of the University of Liverpool 1919-1926, Sometime Strathcona Professor of Pathology McGill University, Montreal: A Memoir. By Marie Adami, together with contributions from others, his friends. And an introduction by Sir Humphry Rolleston, G.C.V.O., K.C.B., M.D. Cloth. Price, $3.50. Pp. 179. New York: Richard R. Smith, Inc., 1930.

Professor Adami taught at McGill University for more than twenty years. He contributed greatly to the literature of his subject. He realized the important part that pathology must play in the growth and the application of medical science, and toward the end of his life he edited "The War Story of the Canadian Army Medical Corps." He was unanimously elected vice chancellor of the University of Liverpool in June, 1919, and he carried on his work in this field until his death in 1926. The memoir is presented chronologically in relationship to the cities and the educational institutions with which he was associated. It includes also a list of his publications and estimates, by his colleagues, of his work. Pathologists, and all of those whose lives brought them into relationship with this distinguished man, will surely find in the volume much of interest.

Handbook of the Vaccine Treatment of Chronic Rheumatic Diseases. By H. Warren Crowe, D.M., B.Ch., M.R.C.S., Director of the Charterhouse Rheumatism Clinic. Paper. Price, 80 cents. Pp. 52. New York: Oxford University Press, 1930.

The author assumes that all rheumatic diseases are bacterial in origin. He recognizes three types: fibrositis, osteoarthritis and rheumatoid arthritis. From the standpoint of treatment he considers a differential diagnosis of no especial importance, as the same treatment is given to the various forms. Streptococci derived from the intestinal tract are responsible for fibrositis and osteoarthritis, and a white staphylococcus, which he designates *Micrococcus deformans*, the etiologic factor in rheumatoid arthritis. In the light of blood culture by Cecil and joint culture by Shand in rheumatoid arthritis showing *Streptococcus viridans*, and the negative blood culture obtained in osteoarthritis, it would appear that the author is somewhat confused in his statement. A vaccine is made from each of these germs and given separately to all rheumatic patients. He ascribes his good results to the use of small doses given subcutaneously. The initial dose is from 50,000 to 100,000 killed organisms. The treatments are given daily. The indications for modifying the dosage for the subsequent injection savors of magic rather than of science. He stresses the importance of avoiding a general reaction. The streptococcal vaccine contains 155 strains, "containing all varieties found in chronic rheumatism." The source of these various strains is not clear, but presumably it is the intestinal tract. The treatment in some cases is continued for years. He admits that there is a marked tendency in his cured cases to relapse. The fact that rheumatoid arthritis is characterized by remissions and recurrences may account for some of his apparent cures. This book cannot be recommended. While knowledge of chronic arthritis is limited, some things apparently are fairly clear, and many of the statements made in this treatise indicate that the author has not kept in touch with the literature on this subject. One must, however, admire his faith in his treatment as shown by the last sentence of his book: "I have not the slightest hesitation in saying that the only universally successful treatment for rheumatism is by vaccine, and that if this method were generally adopted, the industrial problem, which is now engaging the attention of almost the whole world, would soon be satisfactorily and completely solved."

Die Hypertoniekrankheiten. Von Dr. Eskil Kylin, Direktor der inneren Abteilung des Allgemeinen Krankenhauses zu Jönköping. Second edition. Paper. Price, 22 marks. Pp. 270, with 28 illustrations. Berlin: Julius Springer, 1930.

This is an extensive monograph dealing with various hypertensive states. All the factors dealing with normal and abnormal hypertension are considered in a clear and orderly fashion. The author quotes extensively from the literature and gives his own opinion, which may or may not agree with other opinions. The method of taking blood pressure, the factors influencing the normal reading, physiologic variations dependent on age, posture, time of day and the taking of food, the changes due to physical and psychogenic stimuli, and the rôle of the blood vessels and heart, are carefully covered in two sections. The author believes that a chemical study of the blood should be included in examination of hypertensive diseases. Exogenous factors are almost as important as the endogenous factors in elevation of blood pressure. The endocrine glands probably have some influence in elevating blood pressure, but just how much is not definitely known. Heredity is of course important. Essential hypertension is the result of functional disturbances in the blood vessels and leads to contracted kidneys. The author states that all attempts at ascribing hypertension to disease of the kidneys have met with poor results. Experimental work has not yielded as much as hoped for. Because of the association of hypertension with certain forms of acute nephritis and all chronic forms, the author devotes considerable space to a discussion of renal lesions, especially those complicated with arteriolar and capillary changes. The subjects of diagnosis and treatment are covered fairly well. This book should be of especial interest to one who is making a study of hypertension.

The Biological Basis of Human Nature. By H. S. Jennings, Henry Walters Professor of Zoology and Director of the Zoological Laboratory in the Johns Hopkins University. Cloth. Price, $4. Pp. 377, with 51 illustrations. New York: W. W. Norton & Company, Inc., 1930.

The introductory portion, which is about half of the book, consists of a presentation of the laws of heredity as determined by genetics, explaining both the mendelian theory of inheritance and the inheritance of characteristics governed by the x-chromosome. Professor Jennings points out that behaviorists and eugenicists are equally in error; that heredity and environment both are needed to explain the mutations to which species are subject. His speculations as to the method, the desirability and the results of controlled inheritances in controlled environments, and other effects on the individual and on society, are amazingly interesting.

Die Knochen- und Gelenktuberkulose: Kurze Darstellung der Pathogenese, der allgemeinen Diagnostik und der Behandlung. Von Dr. Rudolf Nissen, Privatdozent f. Chirurgie, Oberarzt der chirurgischen Universitatsklinik der Charité, Berlin, und Dr. Paul Meyer-Ruegg, Assistent der chirurgischen Universitätsklinik, Zurich. Tuberkulose-Bibliothek, Beihefte zur Zeitschrift für Tuberkulose, Nr. 36. Herausgegeben von Prof. Dr. Lydia Rabinowitsch. Paper. Price, 7 marks. Pp. 54, with 30 illustrations. Leipzig: Johann Ambrosius Barth, 1930.

This treatise covers in a concise manner the origin, pathology and course of bone and joint tuberculosis. Treatment and diagnosis are also given due attention. The work is well adapted to the needs of the student and practitioner because of the terse style and clearness of expression. The authors quote freely from other writers, giving full credit in the appended index.

Dosage Tables for Rontgen Therapy. By Professor Friedrich Voltz, Head of the Radiological Department, University Clinic for Women, Munich. Translated from the second German edition. Cloth. Price, $2.50. Pp. 120, with 21 illustrations. New York: Oxford University Press, 1930.

This valuable and thorough work is quite technical in description but at the same time is arranged in such a manner as to be readily understandable. The arrangement of the table dosages makes a handy reference. The description of the manner of obtaining these dosages indicates exhaustive work by the author. The book should be of great aid in accomplishing the desired result in roentgen therapy.

Miscellany

THE SMALLPOX EPIDEMIC AMONG THE MANDAN INDIANS IN 1837

WILLIAM ALLEN PUSEY, M.D.
Chicago

In the Mississippi Valley Historical Review, September, 1930, Dr. M. M. Quaife, the eminent historian of the Northwest, has printed the part of the journal of Francis Chardon in which is included Chardon's record of the epidemic of smallpox among the Mandans and other Indians of the upper Missouri River in 1837. The journal is a striking narrative of the hardships and dangers endured by those pioneers of the West, the fur traders, and of the resourcefulness and courage that were required to meet them. It is a brief document, which would be in its entirety interesting to any one; but the peculiar interest for the physician, of course, lies in the vivid impression that the entries in the journal concerning the smallpox give of the ravages of an unfettered smallpox epidemic among a primitive people. It is a picture merely in outline, but in bold vigorous outline, of the stark, hopeless terror of a people in the presence of a hideous disease against which they were helpless. Chardon and the few other whites who were involved in the situation naturally denied that they had anything to do with the introduction of the disease, but the Indians forced this charge on them and, as Quaife says, "They were correct in this belief; the steamboat *St. Peters*, whose arrival at Fort Clark on June 28, on the return voyage from Fort Union, as noted by Chardon, introduced the epidemic to the Indians."

The epidemic has been mentioned, according to Quaife, in numerous journals. One of the descriptions is by Audubon, but Audubon's description is taken from this same Francis Chardon. Chardon's journal is preserved in the Manuscript Division of the Library of Congress.

Chardon was a fur trader in the upper Missouri region for at least twenty years preceding 1848, when he died. There is other evidence besides his journal to indicate the excellent quality of the man. He was in charge of the fur post, Fort Clark, 55 miles above the present-day Bismarck, North Dakota, on the Missouri River, where his only communication with civilization was the annual boat from St. Louis. Chardon's journal throughout indicates the painstaking care on his part. At the beginning of each month he set down the month and, after it, the number of days in it, as, for example, "June 30 days." At the end of the month there is always the entry showing the number of rats killed. Thus, at the end of the notes, on Monday, the 31st, is the entry "killed 61 rats this month—total 1,778." He was a careful recorder, whose entries are to be respected. The diary was written at Fort Clark and parts of it, from which the selections are reprinted, were dated in July, August and September, 1837.

As Quaife says, "The Mandan tribe, like the army of Sennacherib, was practically blotted out, and the sufferers on the upper Missouri knew as little of the nature of their affliction as did the ancient Assyrians."

The account begins with Chardon's entry, "Wednesday, 28 (June). The S. B. [steamboat *St. Peters*] arrived from above at 6 a. m.—and started 7 a. m.—The agent distributed out the few presents to the Rees and gave them a few words of good talk, and departed." From here on, I have selected only references in the journal that have to do with the smallpox.

"(July) Friday 14. A Young Mandan died today of the Small Pox—several others has caught it.

"Monday, 17. An other Case of small pox broke Out to-day at the Village.

"Tuesday, 25. Several young Men Arrived from the dried Meat Camp. . . . They say that the small pox has broke out at the Camp [the meat camp.]

"Thursday, 27. The small pox is Killing them off at the Village, four died to day.

"Friday, 28. The Mandans and Rees gave us two splendid dances, they say they dance, on account of their Not haveing a long time to live, as they expect to all die of the Small Pox.

"Sunday, 30. An other report from the GrosVentres to day say, they are Arrived, at their Village, and that 10 or 15 of them have died, they threaten Death and Distruction to us all at this Place, saying that I was the Cause of the small pox Makeing its appearance in this Country—One of Our best friends of the Village (The Four Bears) died today, regretted by all Who Knew him.

"(August) Saturday, 5th. News from GrosVentres. . . . a Great Many of them have died of the Small Pox—several Chiefs Among them, they swear vengeance against all the Whites, as they say the small Pox Was brought here by the S. B.

"(August) Monday 7. Six more died to day.

"Tuesday 8. Four more died to day—the two thirds of the Village are sick. . . . The small Pox has broke Out at the Little Mandan Village, three died yesterday, two chiefs.

"Wednesday 9. Seven more died to day.

"Thursday 10. All the Rees that were encamped in the Mandan lodges, except a few that are sick, Moved down to the Island hoping to get rid of the small Pox.

"Friday 11. Mandans all crossed to the other Side of the river to encamp—leaving all that were sick in the village, I Keep No A/c of the dead, as they die so fast it is impossible—

"Sunday 13. An Old fellow who has lost the whole of his family to the Number of 14, harrangued today, that it was time to begin to Kill the Whites.

"Monday 14. The Wolf chief An other dog from the Little Village, came to the Fort Naked With his gun cocked, to Kill one of us, We stopped him.

"Tuesday 15. . . . it appears that the small Pox has broke Out Amongst the Sioux, As Some of the Party, on their way back Was taken sick at Grande River, having Caught the disease from those that they butchered.

"Wednesday 16. Several Men, Women, and children that has been abandoned in the Village Are laying dead in the lodges, some Out side of the Village, others in the little river Not entered, which Creates a Very bad Smell all Around us—A Ree that has lost his wife and child threatened us to day—We are beset by enemies on all sides expecting to be shot every minute.

"Thursday 17. The Indians lying off every day—W[h]ere the disease will stop, I Know Not—A Young Ree for several days has been lurking around the Fort, Watching a good opportunity to Kill Me, but not finding a good chance, this morning he Came, full intent, he sit himself down in front of the Fort gate, on the Press, and Waited a few Minutes for me to go Out, in the Mean time one of My Men a Dutchman, John Cliner—stepped out and sat himself down a long side of the Indian, after setting a few Minutes, he got up to Come in the Fort, he only Made five paces When the Indian shot him in the back bone and Killed him instantaniously, he Made Off Immediately—We pursued him after shooting at him, but Without effect—got as far as the little river, . . . on Arriveing there he Made a stop, and hollowed to us that, that was the place he wanted to die. Garreau *Cesar* like approached in 15 paces of him and shot, the contents knocked him Over. . . . The Mother of the fellow We Killed Came to the Fort crying, saying that she wanted to die also, and wished for us to Kill her. Garreau stepped up, and With his tommahawk would have Made short of the Old Woman, but was prevented.

"Saturday 19. A Mandan And his Wife Killed themselves yesterday, to Not Out live their relations that are dead. . . . I was in hopes that the disease was almost at an end, but they are dying off 8 and 10 every day—and new cases of it daily—W[h]ere it will stop *God* only Knows—

"Sunday 20. Three more died in the Village last Night. The Wife of a Young Mandan that caught the disease Was suffering from the pain, her husband looked at her, and held down his head, he jumped up, and said to his wife, When you Was Young, you were hansome, you are now ugly and going to leave me, but No, I will go With you, he took up his gun and shot her dead, And With his Knife ripped open his Own belly—two young men (Rees) Killed themselves to day, one of them stabbed himself With a Knife, and the other with an arrow. . . . A young Ree that has been sick for some time with the small pox, and being alone in his lodge, thought that it was better to die, than to be in so much pain, he began to rub the scabs untill blood Was running all over his body—he rolled himself in the Ashes, Which almost burnt his soul Out of his body—two days after he was perfectly Well, it is a severe operration, but few are disposed to try it—however it proved beneficial to him—

"Monday 21. . . . An Indian Came and told Me to be on My guard—as the fellow above mentioned, is determined to Act as his brother, to Kill One of us, And then die, . . . May he change his notion is the wish of your Humble Servant.

"Tuesday 22. The disease still Keeps ahead 8 and 10 die off daily, thirty five Mandans (Men) have died, the Woman and Children I keep No Account of.

"Thursday 24. Seven More died at the Village last Night, and Many More at the Ree camp at the point of Woods below. The fellow that we Killed on the 17th all his band Came to day to smoke With us and Make Peace, how long it will last I Cannot tell, however We Must put up With it, good or bad—

"Friday, 25. An other Mandan chief died to day—(The Long Fingers) total Number of Men that has died—50, I have turned Out to be a first rate doctor St Grado, an Indian that has been bleeding at the Nose all day, I gave him a decoction of all sorts of ingredients Mixed together, enough to Kill a Buffaloe Bull of the largest size—I done it out of experiment And Am Content to say, that it proved effectual, the Confidence that an Indian has in the Medicine of the whites, is half the Cure.

"Saturday 26. A young Ree that has the Small Pox, told his Mother to go and dig his grave, she accordingly did so—after the grave Was dug, he walked With the help of his Father to the Grave, I Went Out With the Interpreter to try to persuade him to return back to the village—but he would not, Saying for the reason that all his young friends Were gone, And that he wished to follow them, towards evening he died—

"Monday 28. Three More fell sick in the Fort to day—My Interpreter for one, if I loose him I shall be badly off, the bad Weather continued all day—and no Prospects of Clearing off—

"Tuesday 29. An Indian Vacinated his child, by Cutting two small pieces of flesh Out of her Arms, and two on the belly—and then takeing a Scab from One, that Was getting Well of the disease, and rubbing it on the Wounded part, three days after, it took effect, and the child is perfectly Well—

"Thursday 31. A Young Mandan that died 4 days ago, his Wife haveing the disease also Killed her two Children, one a fine Boy of eight years, and the other six, to complete the affair she hung herself.

"Month of August I bid you farewell With all My heart, after running twenty hair breadth escapes, threatened every instant to be all Murdered, however it is the Wish of [your] humble Servant that the Month of September Will be More Favorable, the Number of Deaths up to the present is Very Near five hundred. The Mandans are all Cut off except 23 young and Old Men.

"(September) Sunday 3. A Young Mandan came to pay us a Visit from the Little Village, he informes us, that they are all Most all used up, and that it is his opinion that before the disease stops, that there will not One be left, except 8 or 10 that has Weathered out the Sickness—

"Tuesday 19. I was Visited by a Young fellow from the little Village, he assures Me that there is but 14 of them liveing, the Number of deaths Cannot be less than 800—What a bande of rascals has been used up—

"Thursday 21. The Mandans fearing their Allies, the Rees should unite With the Sioux, have all fled to the Opposite Side of the river, what their intention is I know Not, but the few that are left (41), Are Miserable, surrounded on all Sides."

The miserable wretches for the most part were voiceless and could only indicate their abject wretchedness and hopelessness by committing atrocities on themselves and their people. But they had one spokesman, 4 Bears—a chief to whose good character Chardon gives testimony in this diary—who was able to describe the calamity in words that enable us to realize the awful anguish of the Indians. Of this, Dr. Quaife, in a personal communication, says, "I should like also to call your attention to the speech of 4 Bears, printed on page 299. It seems to me an unusual example of Indian eloquence." It is recorded at the end of Chardon's journal.

"SPEECH OF THE 4 BEARS, A MANDAN WARRIOR, TO THE ARRICAREES AND MANDAN—30TH JULY, 1837

"My Friends one And all, Listen to what I have to say—Ever since I Can remember, I have loved the Whites, I have lived With them ever since I was a Boy, and to the best of My Knowledge, I have Never Wronged a White Man, on the Contrary, I have always Proctected them from the insults of others, Which they Cannot deny, The 4 Bears Never saw a White Man hungry, but that he gave him to eat, Drink, and a Buffaloe skin to sleep on, in time of Need, I was always ready to die for them, Which they Cannot deny, I have done everything that a red Skin could do for them, And how have they repaid it! With Ingratitude! I have Never Called a White Man a Dog, but to day I do Pronounce them to be a set of Black harted Dogs, they have deceived Me, them that I Always Considered as Brothers, has turned Out to be My Worst enemies, I have been in Many Battles, and often wounded, but the Wounds of My enemies, I exhalt in, but to day I am Wounded, And by Whom, by those same White Dogs that I have Always Considered, and Treated as Brothers, I do Not fear Death My friends, You Know it, but to *die* With My face rotten, that even the Wolves will shrink With horror at seeing Me, And say to themselves, that is the 4 Bears the 4 Bears the Friend of the Whites—Listen well what I have to say, as it will be the last time you will hear from Me, think of your Wives, children, Brother, Sisters, Friends, and in fact all that you hold dear, are all Dead, or Dying, with their faces rotten, caused by those dogs the whites, think of all that My friends, and rise all together and Not leave one of them Alive, The 4 Bears Will act his part."

To find as poignant a description of overwhelming grief as this, one must go to the Greek tragedies.

Medicolegal

Sale of Drugs by Itinerant Vender Prohibited

(J. R. Watkins Co. v. Brown et al. (La.); 126 So. 587)

Section 12 of the medical practice act of Louisiana, provides as follows:

> That any itinerant vendor of any drug, nostrum, ointment or application of any kind, intended for the treatment of disease or injury, or who may by writing, print, or other methods, profess to cure or treat disease or deformity by any drug, nostrum, manipulation, or other expedient in this state, shall, if found guilty, be fined . . . or shall be imprisoned . . .

The J. R. Watkins Company entered into a contract with one Robert Lee Brown, one of the defendants in this case, to sell to Brown certain drugs, or medicines, on the condition, among others, that he make at least four times a year "a thorough and personal canvass" of the territory assigned to him for the purpose of selling these medicines. Brown was unable to fulfil the terms of the contract and suit was instituted against him, and his sureties, by the Watkins Company. The lower court gave judgment for Brown, apparently on the ground that the contract was illegal as proposing the itinerant vending of drugs in contravention of the section quoted, and the Watkins Company appealed to the Court of Appeals of Louisiana, First Circuit.

The object of the medical practice act, said the court, was to regulate the practice of medicine by competent physicians or surgeons and to prevent its practice by unauthorized or incompetent persons. The attempt made in section 12 to suppress itinerant venders of drugs was obviously incorporated in the statute for the prevention of the practice of medicine by quacks and mountebanks and such incorporation does not render the act unconstitutional. Counsel for the company contended that there was no penalty imposed for the mere *vending* of drugs, ointments and nostrums. The contention was that the only offense denounced is professing to prescribe for or treat. The section, said the court, denounces the vending of drugs or nostrums by itinerant venders as a crime. It also provides against the professing, by printing or writing, to cure disease or deformity by manipulation or other expedient. The penalty is prescribed against the offender who violates the provisions of the section in either of the ways stated. The words "profess to cure," continued the court, apply also to the mere vending of the drugs, since no sales of the nostrums would be possible unless the purchaser was promised a cure. Of necessity, such an affirmance by the itinerant vender must be implied in every sale. The word "profess," taken in its general sense, means "to acknowledge" "to avow," "to affirm." Every sale must necessarily carry an "avowal" or "affirmance" of the curative virtues of the nostrum. While section 12 of the act is not perfect in point of diction or grammatical construction, the court said, the foregoing construction carries out the legislative purpose, which was to prevent the practice of medicine by the unqualified and the unauthorized.

The Watkins Company contended, finally, that the section in question interfered with interstate commerce and was therefore void. This section, the court said, was enacted for the protection of the public health of the state as a police regulation and is not subject to the objection made.

The appellate court could find no error in the record and the judgment of the trial court was affirmed.

Refusal to Accept Treatment in Compensation Case

(Hudyck v. Wyoming Shovel Works (Pa.), 149 Atl. 312)

Hudyck, while an employee of the defendant company in 1917, lost the sight of his left eye in an industrial accident and was awarded compensation for partial disability. He returned to work for the defendant company and so continued until 1925, when he lost the sight of his right eye, as a result of sympathetic infection developed from the eye first injured. He then petitioned the compensation board to review and modify the compensation awarded him in 1917. The referee to whom the petition was referred awarded him compensation for total disability. The compensation board upheld the award and its action was affirmed by the court of common pleas, Luzerne County. The employer and its insurance company thereupon appealed to the Supreme Court of Pennsylvania, contending that no additional compensation should have been awarded by the referee. They alleged, among other things, that the employee failed to follow the advice of his physician, in 1917, to have the left eyeball removed to prevent infection of the other eye and that that failure created "the equivalent of a refusal to neglect to accept reasonable medical treatment" and resulted in a forfeiture of compensation under section 306(e) of the workmen's compensation act.

Section 306(e) does not apply to this particular situation, said the Supreme Court. A forfeiture of compensation can follow only, in the words of the act, "if the employee shall refuse reasonable surgical, medical, and hospital services, medicines and supplies, tendered to him by his employer." The record does not disclose tenders of that nature by the employer, and the physician who attended the employee was not provided or secured by the employer. The physician whom the employee consulted in 1917, and who testified at the hearing before the referee, recommended the removal of the blind eye; but, as the evidence discloses and the referee found, it does not appear that the employee was made to understand that failure to remove the eye would result in loss of sight in the other eye.

The judgment of the court below was accordingly affirmed.

Society Proceedings

COMING MEETINGS

American Orthopsychiatric Association, New York, February 20-21. Dr. George S. Stevenson, 370 Seventh Ave., New York, Secretary.

American Society for the Study of Disorders of Speech, Chicago, December 30-January 1. Dr. Sara M. Stinchfield, Mount Holyoke College, South Hadley, Mass., Secretary.

American Society of Tropical Medicine, Cleveland, December 27-30. Dr. Edwin Peterson, U. S. Naval Hospital, Washington, D. C., Secretary.

American Student Health Association, New York City, December 29-30. Dr. D. F. Smiley, Cornell University, Ithaca, N. Y., Secretary.

Society of American Bacteriologists, Boston, December 29-31. Dr. James M. Sherman, Cornell University, Ithaca, N. Y., Secretary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Issues of periodicals are kept on file for a period of five years only. *Requests for issues of earlier date cannot be filled.* Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending, but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

American Journal of Diseases of Children, Chicago

40: 941-1162 (Nov.) 1930

*Effect of Phosphorus in Rickets. E. L. Compere, Chicago.—p. 941.

Enlargement of Thyroid Gland in Children. A. Topper and H. Mulier, New York.—p. 974.
*Immunity: III. Effect of Diseases Other Than Diphtheria on Schick Test. B. Eddy and A. G. Mitchell, Cincinnati.—p. 985.
Id.: IV. Effect of Diseases Other Than Scarlet Fever on Dick Test. B. Eddy and A. G. Mitchell, Cincinnati.—p. 988.
*Milk Sugar in Infant Feeding. B. W. Jarvis, New York.—p. 993.
Mental and Physical Development of Children Prematurely Born. G. J. Mohr and P. Bartelme, Chicago.—p. 1000.
Carbon Dioxide Absorption Curve of Infants Fed Lactic Acid, Hydrochloric Acid and Boiled Cow's Milk. D. C. Darrow, New Haven, Conn.—p. 1016.
Development of Scarlet Fever Rash and of Positive Skin Reaction. T. Toyoda and Y. Futagi, Dairen, Manchuria.—p. 1024.
Effect of Tonsillectomy and Adenoidectomy on Diphtheria Immunity. K. B. Geddie, Rochester, Minn.—p. 1032.
Rapidity of Immunization with Diphtheria Toxoid. M. Cooperstock, Ann Arbor, Mich., and G. F. Weinfeld, Ravinia, Ill.—p. 1035.
Bile Salt Hemolysis in New-Born Infants and Inhibition by Blood Serum. H. N. Sanford, M. M. Crane and E. I. Leslie, Chicago.—p. 1039.
Lateral Sinus Thrombosis Complicating Masked Mastoiditis: Case with Secondary Subarachnoid Hemorrhage. I. J. Klein and M. Lederer, New York.—p. 1045.
Massive Suprarenal Hemorrhage in New-Born Infant: Four Cases. D. P. Arnold, Buffalo.—p. 1053.
Thrombosis of Dura Mater Sinuses from Jugular Endophlebitis. A. Hymanson, New York.—p. 1058.
Acute Hemolytic Anemia in Childhood. S. D. Lazarus, New York.—p. 1063.
Early Case of Pyloric Stenosis. E. Caulfield, Hartford, Conn.—p. 1069.
Behavior Problems of Children: Delinquency. I. S. Wile, New York.—p. 1076.
George Armstrong. J. Ruhräh, Baltimore.—p. 1094.

Effect of Phosphorus in Rickets.—In the studies made by Compere, phosphorus alone was not sufficient medication to bring about healing in severe cases of infantile rickets in which there had been no initial stimulation from ultraviolet rays or from cod liver oil. Cod liver oil administered alone to infants with severe rickets, in a dosage of from 3 to 6 teaspoonfuls daily, brought about healing in most of the cases, although in two cases rickets had developed in spite of daily doses of cod liver oil for periods of several months. Phosphorus administered in cases in which cod liver oil had been given and in which its administration was continued and other conditions, such as diet and home hygiene, remained the same, brought about prompt healing of the rickets, and increased calcification of the shafts of the bones. When patients had received elementary phosphorus in the form of one-hundredth grain, or 0.6 mg., pills (two such pills each day) for several months without improvement in the roentgenographic appearance of the bones, the healing response to the addition of cod liver oil was slow and the cure of the rickets sometimes delayed for several months, although in every case so studied healing eventually occurred. The combination of cod liver oil and of phosphorus administered to patients with rickets who had not received previous antirachitic treatment, even though this therapy was begun in the late fall or winter months when the incidence of rickets is known to be high, brought about prompt healing with marked calcification and increased density of all the bones studied by means of the roentgen rays. The combination of cod liver oil and phosphorus produced more prompt and more certain healing of rickets than did cod liver oil alone.

Diphtheria of Umbilicus.—The case of an infant with umbilical diphtheria complicated by postdiphtheritic paralysis and myocarditis is reported by Montgomery, with complete bacteriologic and pathologic observations and a brief review of the literature. It has been impossible to discover in the literature another case of diphtheria limited solely to the umbilicus in which there were myocardial or neurologic complications.

Effect of Diseases Other Than Diphtheria on Schick Test.—A study made by Eddy and Mitchell in 358 cases of measles, scarlet fever, poliomyelitis, varicella and pertussis showed that these diseases do not affect the Schick test; that is, there is no difference between the skin reaction to diphtheria toxin during the acute febrile and the convalescent stages.

Milk Sugar in Infant Feeding.—Jarvis urges a more common use of lactose in infant feeding, based on the following observations: Lactose is well tolerated by the infant when the other elements of formulas are rendered more available for digestion; and it may be increased to amounts of the eventual formula in 10 Gm. doses (i. e., one level tablespoonful) at three-day intervals with safety. Boiling and stirring the formula for three minutes render the protein and fat of cow's milk more available for digestion by making it a more favorable medium for the administration of lactose than unboiled milk. The lactose-fed infant resembles but does not equal the breast-fed infant in firmness of tissues and resistance toward infections. The danger of sudden dehydration with acidosis in the presence of parenteral infection is less acute in lactose-fed infants than, as is well known, in infants fed on vegetable sugar. This is probably due to tissues of less water content normally. Age-weight for age-weight, the lactose-fed infant possesses more living tissue than does the infant fed on vegetable sugar. This is due to the lower water content as well as to the lower fat content of the tissues of the infant fed on milk sugar. Lactose formulas facilitate complementary and supplementary feedings with less danger of refusal by either the breast-fed or the bottle-fed infant. Lactose formulas lessen the dangers of the development of habitual anorexia or constipation. As a source of galactose for the development of the central nervous system, lactose is especially desirable as a sugar for modified feeding in an optimal amount.

Diverticula of Stomach. M. J. Geyman, Santa Barbara.—p. 813.
Dystocia Due to Fetal Ascites: Case. J. N. Ewer, Oakland.—p. 814.

Toxemia and Migraine Due to Food Allergy.—Rowe again calls attention to allergic toxemia due to food allergy and emphasizes the frequency of migraine due to food allergy, and the occurrence of certain cases of neuralgia arising from the same cause. The treatment of allergic toxemia and migraine due to food allergy is carried out by elimination diets modified according to the patient's history of food disagreements or by any positive skin reactions obtained on the patient. Good results demand strict adherence to the method described in former articles. The use of peptone subcutaneously has also been of benefit in controlling mild symptoms due to slight or obscure food sensitizations.

Treatment of Late Syphilis with Single Strain of Malaria.—Analytic evaluation of therapeutic results in 400 cases of dementia paralytica and cerebrospinal syphilis leads Moore to the conclusion that malaria treatment is able to support and revitalize physiologic defense mechanisms in many different types of late syphilis; that malaria treatment may be useful wherever there is gradually developing syphilitic weakness. The use of malaria treatment should be considered wherever and whenever physiologic defense mechanisms give signs of failure in their struggle against syphilis.

Rural Obstetrics.—Peck discusses home delivery procedures, meeting obstacles that come up under such conditions, with particular reference to actual experience in what might be called a cross section of the general population of a state presenting social and economic environments such as are found in Utah. This report covers 1,000 deliveries, in which series there was the loss of 1 mother. Only five patients were sent to the hospital. One patient died because of premature separation of the placenta at eight months. There were two complete lacerations in spontaneous vertex deliveries, blotting paper type. There were three in breech deliveries, all primiparas, four with satisfactory repair, one with some sphincter unreliability. Two sections were done in women with grossly deformed pelves. Two patients with severe infections were sent to the hospital, one of the patients having a pelvic abscess and the other a septic type of infection; both patients recovered. One antepartum fever patient and one preeclamptic patient were sent to the hospital, but each had a normal puerperium and a live baby. There were twelve patients who required uterine packing for control of hemorrhage. Five patients had breast abscesses in the first six weeks after delivery. About 10 per cent of the patients required versions, forceps or other obstetric operations. With the exception of the five hospital patients, these patients were delivered in home surroundings, such as in homesteaders' dirt-floored cabins, or in Japanese boarding houses, or wherever they were found. The charges per baby (including nursing, physician, housekeeper and incidentals) rarely exceeded the sum of $65. Peck says that every young physician starting to do general practice, and particularly obstetrics in rural communities, should be associated with an older physician who has had a large experience along that line. Any country doctor, if he is practicing obstetrics because he likes the work (and not because he must in order to hold his families), can show results in low mortality rates that will measure up most favorably to the rates in general hospitals. Other things being equal, a woman's own bed is not at all a bad place for her in which to have a baby.

Plasma-Protein Loss with Edema but Without Proteinuria.—The six cases studied by Bennett et al. definitely support the theory that depletion of plasma proteins from any cause will lead to the production of edema. Three of the patients had ascites with high protein content; in the others there was extensive ulceration of the stomach presumably leading to long-continued loss. The cases presented striking similarities to the group often described as "nephrosis." Albuminuria, however, was absent and the blood cholesterol was within normal limits, whereas in nephrosis it is raised. In not one of these patients was there evidence of renal damage. The urine was free from albumin, casts, red blood cells or any abnormal constituent. In three of the cases death occurred, and at the necropsy the kidneys were found to be normal. In the others, tests of renal efficiency, such as the urea concentration and the water elimination test, failed to demonstrate any renal lesion. Admitting that such tests are usually negative in early nephrosis, the postmortem observations in three of the present cases, and the constant absence of proteinuria, may be taken as fairly conclusive evidence that the kidneys were normal in all. The authors therefore assume that in the human subject the diminution of plasma proteins, even for a considerable time, does not produce changes in the kidney.

Dick Test in Pregnancy end Relation to Puerperal Sepsis.—The Dick test was performed by Baird and Cruickshank on 600 pregnant women, of whom 22 per cent reacted positively, the incidence and intensity of positive reactions being greater in primiparas, irrespective of age, than in multiparas. Among multiparas the proportion of strongly positive reactors decreased with increasing age; so also did the incidence of puerperal sepsis, whereas both remained constant for all ages in primiparas. A correlation between a positive Dick test and susceptibility to puerperal sepsis was thus suggested but was not supported by further analysis. Previous streptococcal infection—scarlet fever, tonsillitis, puerperal sepsis—did not appear to influence the reaction to the Dick test. On the other hand, the reaction became negative when Dick-positive patients who had puerperal sepsis, however, were retested immediately after the pyrexia subsided. The puerperia of 500 women in the series were investigated. When all cases of puerperal pyrexia, whether notifiable or not, were divided into puerperal sepsis and pyrexia due to other causes, the analysis showed that women who reacted positively to the Dick test were not more liable to develop puerperal sepsis than were negative reactors. However, infection when it occurred tended to be more severe in the Dick-positive than in the Dick-negative cases. An investigation of the factors predisposing to puerperal sepsis showed that sepsis was much more frequently associated with a difficult or mismanaged labor and/or poor health than with a positive reaction to the Dick test.

Megacolon.—The essential lesion of the colon in the case described by Starling was a volvulus of the sigmoid flexure which had never become so complete as actually to occlude the lumen of the bowel. The patient, aged 48 years, had been delicate all her life and had suffered from constipation and sickness, especially in childhood. Her present trouble began at 24 years of age when she saw a consultant for constipation and "nerves"; no cardiac abnormality was noted then. A few years later she had severe gastritis and the heart beat was said to be irregular and intermittent; she rested for five years, with some improvement. At 31 she had a curious heart attack, said by one physician to be functional but by another to be serious, and she was continually in bed after this. In 1914 she saw a London consultant who diagnosed a congenital heart lesion. When Starling saw her first she had been confined either to her room or to her bed for ten years. She was lying on a couch but, even so, showed slight dyspnea. There was some pallor of the face, the general nutrition was good, and the teeth were sound, but there was marked pyorrhea of the gums. The heart was slightly enlarged, there were no bruits, the sounds were tictac, the pulse rate was 150 to 160, and the blood pressure 150 systolic and 110 diastolic. When the patient stood up for some minutes the toes, then the feet, and then the legs became at first congested, then a deep red, then definitely cyanosed. This congestion gradually increased until at the end of ten minutes the upper part of the thighs was a deep red, and the color increased downward to a deep purple. The patient stated that if she stood for much longer the congestion extended up as high as the upper part of the chest, when she would also have marked edema of the left leg and slight edema of the left hand and right leg. The abdomen was not distended but the percussion note all over was hyperresonant. In July, 1925, the first electrocardiogram was taken. This showed a left ventricular preponderance, T_3 inverted, and two extrasystoles in lead II. In March, 1926, she began to have curious fainting attacks and periods of irregular tachycardia. During the next three years these attacks of tachycardia slowly but surely increased in frequency, duration and severity. In November, 1929, she had a severe fainting attack followed by general convulsions and loss of consciousness for some hours, due probably to a cerebral embolus. In the early part of 1930 the attacks of tachycardia were almost continuous, and early one morning in April she was found to have died quietly about one hour after she had been seen to be sleeping peacefully. A partial postmortem was allowed. A double loop or volvulus occupied the greater part of the abdomen, the distal part arising from the sigmoid flexure and the proximal part ending close to the distal end, in the lower part of the ascending colon. The descending and transverse parts of the colon were twice (and in parts three times) the normal size and the latter was lying high up under the costal margin. Above this again was seen the stomach, the major portion of which was on the left side at the level of the fifth to the seventh ribs, but the duodenal portion was enormously elongated, stretching across to the right seventh rib in the midclavicular line. The upper limit of the diaphragm on the right side was at the third rib, the liver occupying the space below this, and on the left side was at the fifth rib. The heart was slightly larger than normal, the muscle and the valves apparently were normal.

Herpes Zoster of Fifth Lumbar Nerve.—Waterhouse records the case of a woman, aged 74, suffering from typical herpes zoster, evidently resulting from inflammation of the fifth lumbar nerve root ganglion on the right side. The vesicles covered the dorsum of the foot and of the first three toes, and the inner half of the fourth toe; vesicles were also present on the ventral aspect of the first three toes. In addition, they occupied the whole of the outer surface of the leg below the knee, two particularly prominent collections being present in the neighborhood of the head of the fibula. But what is of peculiar interest is the fact that in the center of the posterior aspect of the thigh, midway between the fold of the buttock and that of the knee, was situated an oval patch of vesicles measuring 2½ inches from above downward, and about 1¼ inches from side to side: higher up again was another similar but larger patch commencing 1 inch above the termination of the internatal cleft and extending downward and outward, across the buttock, for some 6 inches and being about 2¼ inches in breadth. The importance of this case consists in the light it throws on the sensory distribution of the fifth lumbar nerve, since it is extremely improbable that more than one nerve root was involved.

*Azotemic Nephritis in Typhoid. A. Lemierre and R. Cattan.—p. 335.
Saturnine Nephritis. Pasteur Vallery-Radot and M. Dérot.—p. 341.

Azotemic Nephritis in Typhoid.—In the course of typhoid and paratyphoid, acute nephritic conditions with more or less pronounced azotemia often develop. It is impossible to estimate the frequency of the complication because the symptoms are so general that they often pass unrecognized. Examination of the urine is of no avail, for there is no constant relationship between the azotemia and urinary symptoms. Lemierre and Cattan show, however, that there is a definite clinical syndrome that may be regarded as pathognomonic. The three chief indications are an acute ataxo-adynamia, development of severe digestive disturbances (or aggravation of existing conditions), and a more or less rapid abatement of the fever. The lowered temperature is the most important of the three symptoms and has been found to be constant in azotemic complications of typhoid. The only way the existence of the azotemia can be established definitely is by determining the urea content of the blood. The authors advise careful observation of all typhoid patients so that analysis of the blood may be made whenever the clinical developments suggest the complication of nephritis with azotemia. A urea content of more than 0.5 Gm. in the course of typhoid is indicative of renal disturbances. In the majority of cases these nephritic conditions are benign and as the azotemia disappears the temperature of the patient rises. In some cases, however, the azotemia steadily increases, the temperature falls, and the patient dies before the nature of the complication is suspected.

Abortion and the New Penal Code of Vaud. M. Muret.—p. 689.
*Serology of Tuberculosis. J. L. Dufour and V. E. Badoux.—p. 700.
*Atropine Treatment in Habitual Vomiting in a Nursling. J. Stephani-Cherbuliez.—p. 720.

Serology of Tuberculosis.—Dufour and Badoux conducted a series of experiments with 100 tuberculous patients, or patients believed to be tuberculous. Each was given simultaneously a complement fixation test (Besredka method), a Vernes resorcinol flocculation test, and an erythrocyte sedimentation test (Fahraeus-Westergren method). The tests were made with blood from the same venous puncture, taken during a period of fasting. They found that among the twenty-eight patients who later died as a result of their tuberculous conditions the proportion of positive reactions to all three tests was extremely high (Vernes, 96.4 per cent; Besredka, 92.8 per cent and sedimentation rate, 92.8 per cent). They observed, moreover, that in general there was a concordance between the serologic reactions and the clinical evolution in individual patients. This is especially true of the Besredka and Vernes reactions. The sedimentation rate often presents anomalies that would be misleading without the evidence of the other reactions; for instance, cachectic conditions often cause a marked decrease in the sedimentation rate, while the Besredka and Vernes reactions remain high, and other influences such as exudates in formation and general pathologic conditions often affect the sedimentation of erythrocytes. The authors admit that in a few cases misleading results were obtained with other tests also, as in the case of a woman whose sedimentation rate alone was positive, both the Besredka and Vernes tests showing definitely negative results, and who died shortly afterward. However, they are convinced that the use of all three tests is usually a reliable method of determining the presence and nature of tuberculosis. In doubtful cases (i. e., hovering between positive and negative) a negative Besredka reaction is more significant than a positive Vernes reaction. Both Vernes and Besredka reactions are more constant than the erythrocyte sedimentation reaction, since the last is more susceptible to the influence of general pathologic conditions. A resorcinol flocculation reaction of more than 30 is almost always certain proof of a progressive tuberculosis.

Atropine for Habitual Vomiting in Nursling.—Stephani-Cherbuliez reports the case of a girl, aged 12 months, who had begun to have habitual vomiting at the age of 6 months immediately after an antivariola vaccination. She was extremely thin and weak, her skin was dry and white, she cried constantly from hunger and thirst, and her sleep was intermittent. Enemas every two or four days produced meager stools that were dry and firm. Several physicians had tried all the usual combinations of diet and medicinal treatment, with no success. The child showed almost absolute intolerance of any form of nourishment. As a last resort, the author tried the following treatment, which proved eminently successful: At first 1 mg. of atropine was given each day, in two granules of 0.5 mg. each, taken morning and evening. The vomiting disappeared at the afternoon and night feedings but persisted in the morning and evening. The daily dose was then increased to 2 mg., 0.5 mg. being administered four times a day. The vomiting immediately ceased, the skin began to regain its moisture, the stools became normal, and the child began to regain her strength and weight. After fifteen days the dose was reduced to 1 mg., after thirty days to 0.5 mg., later to 0.25 mg. After three months the atropine treatment was discontinued. The condition of the patient steadily improved and the vomiting did not recur.

Mercury Exanthems in Children.—Jenny describes his observations on seven children in whom ingestion of an anthelmintic containing mild mercurous chloride caused fever and skin eruptions of the type that are noted in erythema infectiosum. In another case the same rash developed after silver amalgamate had been used for the filling of teeth. It could be demonstrated that those patients were subject to a hypersensitiveness to mercury. The author thinks that such hypersusceptibility is more frequent than is generally assumed.

*Congenital Intestinal Occlusion Due to Malformation of Cecum. E. Santi.—p. *1021.*
Action of Viosterol on Epiphyseal Autoplastic Transplants. D. Vallone.—p. 1029.

Congenital Intestinal Occlusion Due to Malformation of Cecum.—Santi describes a case of congenital intestinal occlusion caused by arrested development and malformation of the cecum. As regards the causes that may have determined the arrested development, the author cannot apply the theories of Tandler and Forssner for in his case there was neither atresia nor stenosis. He might fall back on fetal inflammations (peritonitis, enteritis), which undoubtedly existed, as is shown by the fetal diseases (tuberculosis, syphilis, endocarditis) and which may without doubt be the cause of malformations, but before they can be accepted they must be demonstrated in the case in question, which is, however, *impossible in his case.* He thinks that the condition may be regarded rather as a malformation due to a reversion to a more primitive type, owing to a peculiar and unknown predisposition of the germ cell.

*Bactericidal Potency in Vitro of Blood of Irradiated Rabbits, and Behavior of Certain Septicemic Organisms in Rabbits. P. Marginesu.—p. 917.
Case of Sodiku, or Rat-Bite Fever. F. Stefani.—p. 931.

Bactericidal Potency of Blood of Irradiated Rabbits.—Marginesu found that the blood or the blood serum of rabbits irradiated at various times with ultraviolet rays shows no appreciable differences from the blood and the serum of nonirradiated rabbits, as concerns their bactericidal potency in vitro toward the pneumococcus and the bacillus of hemorrhagic septicemia of rabbits. Nor did the p_H of the blood undergo perceptible variations as a result of the irradiation of the animals. The whole blood (citrated) was found capable of greater bactericidal activity than the serum in both the irradiated and in the nonirradiated rabbits. The behavior in the circulation of certain septicemic organisms possessing high virulence (bacillus of hemorrhagic septicemia of cattle) and the course of infection resulting from these micro-organisms were similar in the rabbits irradiated for a period of fifteen days preceding the infective inoculation and in the nonirradiated rabbits. In rabbits irradiated after the inoculation, the multiplication of the micro-organisms and the deaths of the animals underwent a slight retardation. A somewhat attenuated strain of pneumococcus, type I, inoculated by the intravenous route into irradiated and into nonirradiated rabbits, was isolated from the blood in the first fifteen hours but then disappeared from the circulation almost simultaneously in all rabbits and later reappeared first in the nonirradiated and then, still later, in the irradiated rabbits. Both the irradiated and the nonirradiated rabbits died from pneumococcic septicemia; but in the irradiated animals death occurred a few days later than in the controls—the nonirradiated.

86: 321-344 (Sept. 27) 1930

*Bloodless Treatment of Carbuncle in Rural Communities. C. Pérez-Caballero Palacios.—p. 321.
Present Status on Problems of Infection. M. R. Castex.—p. 323.
Pathogenesis and Treatment of Gout by Mineral Waters. C. García de Cosa.—p. 328.

Bloodless Treatment of Carbuncle in Rural Communities.—Pérez-Caballero Palacios states that in most instances the local treatment of carbuncle is ineffective. General treatment gives better results, because it checks general sepsis. The author advises the following method: As soon as the patient is observed, an intravenous injection of 0.3 Gm. of neoarsphenamine, and six hours later a subcutaneous injection of 10 cc. of anticarbuncle serum, are given. Both injections are repeated next day, the dose of the injection of neoarsphenamine being increased to 0.45 Gm. As local treatment, small compresses soaked in a 2:1,000 solution of mercuric chloride are applied during the first twenty-four hours. During the second day, the local treatment is varied slightly: the surrounding areas of the pustule are protected with an absorbent paper and just one drop of a 1:1,000 solution of mercuric chloride is instilled over the pustule and allowed to evaporate. Then another drop is instilled and so on until 15 drops are administered during the day and another 15 drops during the night. The author has obtained good results in more than twenty cases within two days. The treatment is efficient, painless and economical, and no scar is left. The principal indication for the method is its use in rural practice.

Osteopsathyrosis with Blue Scleras: Treatment. J. Breuer.—p. 1735.
Irradiation in Treatment of Wounds. Axmann.—p. 1735.

Serotherapy of Diphtheritic Paralysis.—Friedemann and Elkeles found that the blood-cerebrospinal fluid barrier is impermeable for antitoxin in normal rabbits and in human beings with diphtheria. This would indicate that it is impossible to influence diphtheritic paralysis by means of therapeutic serum. In contradiction to this theory it was found that the intracerebral diphtheria poisoning of the rabbit can be cured by the intravenous administration of large doses of antitoxin. This apparent contradiction may be explained by the fact that the cerebral diphtheria poisoning makes the blood-cerebrospinal fluid barrier permeable for antitoxin.

Powder or Fat in Care of Skin of Infants?—Bayer shows that the use of powders, that is, dry treatment of the skin of infants cannot be considered a physiologic method. Theoretical reasoning as well as practical experience indicates that, if fatty substances are employed in the care of the infant's skin, inflammations and exudations are prevented more effectively than if powders are used.

JOURNALS ABSTRACTED IN THE CURRENT MEDICAL LITERATURE DEPARTMENT, JULY-DECEMBER, 1930

Abstracts of important articles in the following journals have been made in the Current Literature Department of THE JOURNAL during the past six months. Any of the journals, except those starred, will be lent by THE JOURNAL to subscribers in continental United States and Canada and to Fellows of the American Medical Association for a period not exceeding three days. Two journals may be borrowed at a time. No journals are available prior to 1925. Requests for periodicals should be addressed to the Library of the American Medical Association and should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Thus most of these journals are accessible to the general practitioner.

SUBJECT INDEX

This is an index to all the reading matter in THE JOURNAL. In the Current Medical Literature Department only the articles which have been abstracted are indexed.

The letters used to explain in which department the matter indexed appears are as follows: "BI," Bureau of Investigation; "E," Editorial; "C," Correspondence; "ME," Medical Economics; "ab," abstract; the star (*) indicates an original article in THE JOURNAL.

This is a subject index and one should, therefore, look for the subject word, with the following exceptions: "Book Notices," "Deaths," "Medicolegal Abstracts" and "Societies" are indexed under these titles at the end of the letters "B," "D," "M" and "S." State board examinations are entered the general heading State Board Reports, and not under the names of the individual states. Matter pertaining to the Association is indexed under "American Medical Association." The name of the author, in brackets, follows the subject entry.

For author index see page 2078.

A

A. B. & S.; A. B. S. & C., poisoning in children from, [Aikman] ★1663
A. D. S. Cold and Grippe Tablets, 1444—BI
ABBOTT, LE ROY C., 1512
ABDERHALDEN TEST, Sdrodowski modification in pregnancy, [Segre] 1625—ab
ABDOMEN, acute conditions, costly delays in, [Smith] 156—ab
  acute conditions, purpura simulating, [Fraser] 1299—ab
  acute conditions, x-ray diagnosis, [Laurell] 701—ab
  acute syndrome of cord sections, [Hamant] 1056—ab
  cavity, peptic ulcer perforates, [Singer] 229—ab
  diagnostic investigation, [Toutkowsky] 234—ab
  disorders in children, [Jehle] 460—ab
  Fistula: See Fistula
  injury, hemorrhagic steatopancreatic necrosis after, [Scaglia] 1216—ab
  laparotomy incisions, rectus suture in, [Latzko] 763—ab
  laparotomy, necrosis of wall after, [Hellström] 702—ab
  laparotomy scars, endometriosis, [Keene & Kimbrough] ★1166
  pain, from hepatodiaphragmatic adhesions, [Hinton] ★1744
  pain, of parietal from intra-abdominal origin, sign differentiating, [Rubenstone] ★1803
  pain, syphilitic celialgia, [Turriès] 1054—ab
  purpura as acute emergency of, [Bailey] 1867—ab
  reflexes, loss of, [Hall] ★703
  relationship between nerve plexuses and lymph nodes, [Kiss] 1293—ab
  skin, fat in, [Plaschkes] 901—ab
  surgery, adhesions after, 1119
  surgery, by McDowell, in 1809, 1595
  surgery, for rectal cancer, [Jones] ★1172
  surgery, painful scars, [Bancroft] 824—ab
  surgery, ulcerative colitis complicating [Bargen] 372—ab
  surgery, ulcers after, [Freeman] 1778—ab
  traumatic lesions, [Hyndman] 155—ab
  tumor, lymphangioma, [Hill] 1781—ab
  unusual conditions, [Fisher] 155—ab
  wall, gallstones pass through, [Davis] 1458—ab
ABDOMINAL BAND, for infants, 817
ABIOTROPHY, in children, insulin for, [Careddu] 899—ab
  nervous disease, [Roholm] 461—ab
ABNORMAL, meaning of, 323—ab
ABNORMALITIES: See also Deformities; under names of organs and regions, as Colon; Duodenum; Foot; Hip Joint; Nervous System; Urachus; etc.
  in diabetic children, [Priesel] 829—ab
  relation to physical diagnosis, [Mackmull] 1204—ab
ABORTION: See also under Medicolegal Abstracts at end of letter M
  Commission on, Russia, 1192
  Congress of League for Sexual Reform on, 1191
  criminal, Amante Rongetti, 668; 1452
  criminal, licenses revoked for, 539
  criminal, masseuse sentenced for, 1841
  fibromyoma expelled after, [Borochowitsch] 1461—ab
  from removal of tapeworm, 1041
  in parkinsonism, [Bland & Goldstein] ★473
  in tuberculous, [Matthews & Bryant] ★1711
  infectious, [Sievers] 638—ab; 673
  problem, Berlin, 216
  Roman Catholic Church attitude on, 1191
  therapeutic, [Findley] ★857
  therapeutic, in albuminuria, edema and hypertension, etc., [Huggins & Bucy] ★653
  therapeutic, in congenital hereditary cataract or in brain tumor, [Fleischmann] 1305—ab
  treatment, [Grann-Petersen] 1630—ab
ABORTUS FEVER: See Undulant Fever
ABRAMS Electronic Reactions, 1523—BI
ABSCESS: See also Brain; Douglas Pouch; Lungs; etc.
  after appendicitis, [Tagliavacche] 1541—ab
  agranulocytosis, [Robers & Kracke] ★780
ABSCESS—Continued
  Amebic: See Liver; Lungs
  cold, radical treatment, [Benedetti-Valentini] 1950—ab
  fixation, for congenital cystic lymphangioma, [Suner] 976—ab

  perinephric, [Campbell] 1943—ab
  subphrenic, [Gatewood] 1290—ab; [Dahl] 1306—ab
  subphrenic, with gallbladder empyema, [Polayes & Lederer] ★407
  tuberculous, pelvic, extraperitoneal, [Brady] ★338
ABSORBINE, JR., for ringworm of feet, 433
ABSORPTION of aluminum in body, 1691
  of calcium and phosphorus in rickets, [Peola] 1541—ab
  of dextrose by rectum vs. blood sugar changes, 146; 1283
  of drugs from right ventricular cavity, [Wiggers] 625—ab
  of lead from gastro-intestinal canal, [Miyasaki] 238—ab
  of phenol, 1197
  of ragweed pollen from nose and throat, disappearance after, [Cohen & others] 293—ab; 1456—ab
  of toxins, fatal, in mechanical ileus, [Heusser] 903—ab
ACACIA solution, for invisible writing, [Langen] 1628—ab
ACADEMY: See also American Academy of Ophthalmology and Otolaryngology; Nashville Academy of Medicine; National Academy of Sciences; New York Academy of Medicine; etc.
  Accademia Lancisiana, meeting, 947
  of Medicine, French, 58; 544; 606
ACANTHOSIS nigricans confined to palms and soles, 145
ACAPNIA in postoperative shock, atelectasis and pneumonia, [Henderson] ★572
ACCESSORY SINUSES: See Nose
ACCIDENTS: See also First Aid; Safety; Trauma; Workmen's Compensation Acts; etc.; and under Medicolegal Abstracts at the end of letter M
  Automobile: See Automobile
  aviation, 1924
  aviation, anemia in pilot after, [Midulla] 305—ab
  fatal, increase, Michigan, 601
  Industrial: See Industrial accidents
  Insurance: See Insurance
  street, 18 deaths a day, 1599
ACCOUNTS, bad, losses by, 602
  hospital accounting system, 1433
  Robison National Clearing Company, Inc., 1853—BI
ACETABULUM, fractures from crushing, [Truzzi] 1872—ab
ACETANILID, dangers involved in indiscriminate use of, 1676
  sulphemoglobinemia, [Harrop & Waterfield] ★647
ACETARSONE in malaria, [Bass] ★989
ACETIC ACID: See Acid
ACETONE in Blood: See Blood
  in Urine: See Urine
  solution, alcoholic, of gentian violet in varicose veins sloughs, [Kilbourne] ★787
*di*ACETYLMORPHINE poisoning, Drinker respirator in, [Drinker and others] ★1251
ACETYLSALICYLIC ACID: See Acid
ACHIEVEMENT, professional, determinants, 116—E
ACHLORHYDRIA: See Stomach acidity
ACHYLIA gastrica, differential diagnosis with neutral red, [Streicher] ★326
  gastrica, pepsin in urine [Rothschild 239—ab
  gastrica, relation to pernicious anemia, [Castle] 163—ab, 1289—ab
ACID, acetic, solution for counting leukocytes, 817
  acetic, use in biologic diagnosis of pregnancy, [Laffont] 974—ab
  acetylsalicylic and whisky in asthma, [Beckman], ★1585
  acetylsalicylic, dispensing, 1366
ACID—Continued
  acetylsalicylic, in preventing rheumatic manifestations, [Leech] ★932
  acetylsalicylic, intoxicating effect of using aspirin in Coca Cola, 1366
  acetylsalicylic, nostrum, Asper-Lax, 430—BI
  acetylsalicylic, nostrum Nuremedy, 680—BI
  acetylsalicylic, possible neuritis from overdosage, 614
  acetylsalicylic, sulphemoglobinemia from, [Harrop & Waterfield] ★647
  alkaline meat mixtures, duodenal contents reaction to, [Mettier] 449—ab
  antoxyproteic, in urine, in amentia praecox, [Gullotta] 699—ab
  ash food elements, [Stone] ★711
  barbituric, to prevent cocaine poisoning, 1839—E
  boric, pneumonoconiosis or pulmonary hemorrhage from, 684
  boric, poisoning in children, [Aikman] ★1662
  Carbolic: See Phenol
  *tri*chloracetic, for chemocoagulation of bladder tumors, [Stutzin] 1545—ab
  diallylbarbituric, cardiac irregularities under, [Brow & others] ★715
  diet effect on feces of infants, [Gerstley] 689—ab
  diet in asthma, [Tiefensee] 1462—ab
  diet vs. bone regeneration, [Mondry] 1543—ab
  fatty, becoming available for neutralizing toxins, 664—E
  glycuronic, in urine, significance, 615
  hydrochloric, and diarrhea, [Emery], 1699—ab
  hydrochloric, free, secretion vs. hyperthyroidism, [Brown] 1291—ab
  hydrochloric, in pernicious anemia with achlorhydria, [Davis] 628—ab
  hydrochloric, poisoning in children, [Aikman] ★1662
  hydrochloric, treatment in essential hypertension, [Ayman] ★246; 666—E
  hydrocyanic gas, execution by in state prison, [Hamer] ★661
  hydrocyanic, in viscera at delayed necropsies, 544
  β-hydroxyglutamic in liver active in pernicious anemia, 1509—E
  5-Iodo-2-Pyridon-N-Acetic: See Iopax
  Isoamylethylbarbituric Acid: See Amytal.
  Lactic: See also Milk, acidified
  Lactic, in Blood: See Blood
  lactic, increased formation in muscles of gravidas, [Hoffmann] 1627—ab
  neutralization, value in gastroduodenal ulcers, [Palmer] 1127—ab
  nitrohydrochloric, in hayfever, 1117; [Beckman] ★1585
  phenylcinchoninic, liver atrophy due to, 345—E; [Rabinowitz] ★1229
  Picric: See Trinitrophenol
  sodium pyrophosphate, toxicity, 65
  sulphosalicylic, Albutesta, 1347
  sulphosalicylic, use in determining albumin in spinal fluid, [Berger] 458—ab
  sulphuric, in blood chemistry analysis, [Mathieu] 1130—ab
  sulphurous plus sulphuric, nostrum, Sanovapor, 1365—BI
  tannic, for burns, [Wollesen] 764—ab; [Davidson] 1941—ab
  tannic, removal of tattoo marks, 1763
  tetraiodo-orthosulphobenzoic, disodium salt of, in roentgen diagnosis of synovial adhesions, 1749—E
  vanadic, poisoning from shoe dyes, 739
ACID-BASE EQUILIBRIUM and allergy, [Beckman] ★1582
  in cardiorenal diseases, [Lipets] 1629—ab
  in tuberculosis, [Varela] 1876—ab
ACIDIFIED MILK: See Milk
ACIDOPHILIC cells in thyroid, [Warren] 1296—ab
ACIDOPHILUS: See Bacillus acidophilus
ACIDOSIS: See also Diabetes Mellitus
  allergy and, [Beckman] ★1582
  allergy as special type, [Beckman] 294—ab

MEDICOLEGAL ABSTRACTS

ABORTION: criminal; evidence, other criminal abortions, 1452
  criminal; evidence, prior curretments, 438
  criminal: evidence; statements of woman, 1202
  therapeutic; necessity for, burden of proof, 438
ACCIDENT: automobile; operator's eyesight defective, 960
ASSAULT AND BATTERY: operation, unauthorized as, 436
AUTOMOBILES: operator partially blind; not negligence to ride with, 960
BIRTH: stillbirth; civil liability for, 752
  stillbirth; trauma not proximate cause, 752
BLOOD: loss of, as a "physical injury," 1613
CHIROPRACTIC: electric treatments; right to give, 822
COMMUNICABLE DISEASES: report of; statutory time limit, construction of, 620
COMPENSATION OF PHYSICIANS: attending physician; employment of consultant, effect of, 1371
  contract; estoppel to deny, 1371
  contract; implied termination, 1371
CONTRACTS: accidents not warranted against by surgeon, 1124
  cure not warranted by surgeon, 1124
COPYRIGHT: reprints; distribution without copyright notice as abandonment of copyright, 1045
DAMAGES: fright; when an element, 1123
  failure to discharge duty as an element of, 1614
  mental suffering; when an element of, 1613
  physical suffering as an element of, 1613
DENTAL PRACTICE ACTS: licenses, revocation; employment of unlicensed persons, 1372
  licenses, revocation; provisions penal, 1372
DRUGS: aspirin a "drug"; not a "proprietary medicine," 149
  mistake by pharmacist; liability, 1696
  neoarsphenamine in treatment of "trench mouth," 150
  proprietary; aspirin, 149
DRUNKENNESS: when "under influence of intoxicating liquor," 822
ELECTRIC TREATMENTS: right of chiropractor to give, 822
ELECTRONIC TEST: evaluation of, 969
EPILEPSY: accident caused by; compensability, 1860
EVIDENCE: dying declarations; admissibility of, 620; 1372
  dying declarations: hopelessness of declarant, 620; 1372
  dying declarations; preliminary draft not authorized by declarant, 554
  electronic test; evaluation of, 959
  eyesight, loss of; injured person may testify as to, 1202
  judicial notice; scientific facts, 1372
  roentgenograms; failure to produce, 1202
  scientific facts; judicial notice of, 1372
  statements of patients as hearsay, 1202
  witness, attending physician, opinion evidence, 1371
  witness; conjectures inadmissible, 1614
  witness, expert; competency of, 959
  witness, expert; conjectures inadmissible, 1614
  witness, expert; credibility, 1046
  witness, expert; opinion invading province of jury, 1452
  witness; failure to call, 1202
  witness in criminal insanity proceeding, defendant as, 889
  witness; lay; injured person may testify as to loss of eyesight, 1202
EYE: defective vision; automobile operator; accident, 960
  detached retina; attributed to trauma, 1124
  gonorrheal ophthalmia from towel, 1452
EYE—Continued
  loss of remaining eye in industrial accident, 1938
  ophthalmia neonatorum; failure to use prophylactic, 620
FRIGHT: damages for, when payable, 1123
  not an actionable injury, 960
  proximate legal cause of, 1123
GONORRHEA: ophthalmia from infected towel, 1452
HEALTH DEPARTMENT: osteopath appointed as health officer, 1614
HEMORRHAGE: as a "physical injury," 1613
HERNIA: operation as involving cutting into abdomen, 1695
  strangulation of preexisting, 292
  trauma and preformed sac in relation to, 1695
HOSPITALS, charitable; indemnity insurance, effect on liability, 1860
  electric lights extinguished during operation; liability of lighting company, 1613
  for profit; liability for injury to special nurse, 1772
  for profit; liable for malpractice by staff physician, 1530
  nurses; liability for neglect of, 437
  nurses; special; liability for injury to, 1772
  private; right of municipality to finance, 1123
  public and private differentiated, 1123
  public; criteria of public status, 1123
  public; exclusion of practitioners, 366
  public; osteopaths' right to practice in, 366
INJURY: fright not actionable, 960
INJURIES: physical; loss of blood as, 1613
INSANITY: arrest of insane person without judicial process, 1614
  criminal; commitment though presently sane, 619
  criminal; commitment, trial by jury, 619
  criminal; evidence; defendant as compulsory witness, 889
  criminal; lunacy commission, constitutionality of procedure, 619
INSURANCE: accident; accidental means defined, 1695
  accident; gonorrheal ophthalmia from towel, 1452
  accident; hernia attributed to preformed sac, 1695
  accident; infection following tooth extraction, 1045
  accident; "operation involving cutting into abdomen," 1695
  accident; total disability defined, 890, 1696
  indemnity; effect on liability of charitable hospital, 1860
  indemnity; questioning defendant in malpractice case concerning, 438
  life; cancer and good health, 1529
  life; diabetes, undisclosed by applicant, 70
  life; "good health" defined, 1529
  life; illness between application and issue of policy, 554
  life; representation as to prior medical attendance, materiality of, 821
  life; representations as to prior health, 70; 554; 821
  life; suicide of insured, 437
JURORS: illness of, 554; 1530
MALPRACTICE: adhesive tape; burns in removing, 437
  aggravation of pre-existing injury; liability, 688
  burns in removing adhesive tape, 437
  burns; roentgen rays, 752; 960
  cancer attributed to dental plate, 959
  damages; release of person causing pre-existing injury, 688
  delivery of child; gauze left in vagina, 70
  dentist; cancer attributed to dental plate, 959
  dentist; extraction of wrong teeth, 226
  dentist; hypodermic needle broken in gum, 1046
  employer of physician; liability of, 1201
  examination; fracture of leg as result of, 1201
  examining physician; liability of, 1201
  eye; failure to use prophylactic, criminal liability, 620
  foreign bodies; failure to remove from bronchus before performing tonsillectomy, 1124
  foreign bodies; gauze left in vagina after labor, 70
  foreign bodies; needles, 1046
  foreign bodies; rubber tip from mouth gag in bronchus, 1124
  hypodermic needle; point left in gum, 1046
  hysterectomy, vesicovaginal fistula following, 1613
  indemnity insurance; questioning defendant concerning, 438
  injection, intravenous; local complications, 150
  injury, pre-existing, aggravated by treatment; release of person causing injury, 688
  legal nature of malpractice suit, 226
  limitation of action; accrual of cause of action, 70
  naturopath; standard by which judged, 1860
  nurses; liability of operating surgeon, 437
  operation; authority to operate limited, 436
  operation; fatal tonsillectomy, 1530
  operations; unauthorized, 226; 436
  osteopath; fatal tonsillectomy, 1530
  patient's duty to return for treatment, 226
  res ipsa loquitur, 150; 960; 1613
  roentgen ray burn; res ipsa loquitur, 960
MALPRACTICE—Continued
  roentgen rays; burns; subsequent treatment by another, 752
  roentgen rays; idiosyncrasy to, 752
  staff physician; liability of hospital for neglect by, 1530
  teeth, extraction of wrong, 226
  tonsillectomy, fatal, 1530
  tonsillectomy; performing with foreign body in bronchus, liability for, 1124
  trench mouth, 150
MASTOIDITIS: trauma as cause, 688
MEDICAL PRACTICE ACTS: chiropractic; electric treatment, right to give, 822
  drugs; itinerant vending as violation, 1994
  information; allegations necessary, 226
  licenses, revocation; betrayal of professional secret, 1696
  licenses, revocation, conviction for crime, 1772
  licenses, revocation; employment of unlicensed persons, 1372
  licenses, revocation; provisions penal, 1372
  revocation; gross misconduct, fraudulent representation as to diagnosis, 366
  revocation; misrepresentation as to patient's ailment, 366
NURSES: employment by physician in compensation case, 1772
  liability of physician for acts of, 437
  special; liability for injury to, 103
OPHTHALMIA NEONATORUM: failure to use prophylactic, liability, 620
OSTEOPATHY: exclusion of osteopaths from public hospitals, 366
  health officer; qualifications of osteopath to appointment, 1614
  malpractice; fatal tonsillectomy, 1530
  osteopath as a legally qualified physician, 1614
  right of osteopath to practice in public hospital, 366
PELLAGRA: total disability as caused by, 890
PHARMACY: care required of pharmacist, 1696
  injunction to enforce pharmacy act, 149
POISON: carbolic acid, suicide attributed to, 437
  carbon monoxide and workmen's compensation acts, 554
PRIVILEGED COMMUNICATIONS: common law rule, 1772
SACROILIAC STRAIN: diagnosis by roentgen rays, 1288
SMELL: traumatic destruction of sense of, 889
STILLBIRTH: See Birth
SUICIDE: life insurance in relation to, 437
TEETH: Ludwig's angina after extraction, 1045
  removal of wrong teeth by dentist, 226
TONSILLECTOMY: foreign body in bronchus, 1124
  operation by osteopath fatal, 1530
TRAUMA: detached retina attributed to, 1124
  hernia; preformed sac, 1695
  mastoiditis attributed to, 688
  sacroiliac injury; septic infection aggravating, 1288
  smell, sense of; loss attributed to, 889
VACCINATION: death following; compensable injury, 1938
WILLS: testamentary capacity and arteriosclerosis, 1371
  testamentary capacity and insanity distinguished, 1696
  testamentary capacity and old age, 1371
  testamentary capacity; criteria of, 1696
  testamentary capacity determinable by physical condition, 1371
WORDS AND PHRASES: "abdomen," 1695
  "accident," 292
  "accident arising out of and in course of employment," 554
  "accidental in nature," 70
  "accidental means," 1695
  "conviction," 1772
  "drug," 149
  "external violent and accidental means," 1045; 1452

  "total disability," 70; 890; 1696
  "under the influence of intoxicating liquor," 822
  "wilful betraying of a professional secret," 1696
WORKMEN'S COMPENSATION ACTS: carbon monoxide poisoning of garage employee compensable, 554
  defects of body antecedent to injury, 292
  disability, evaluation of, when due to cumulative effects of injuries, 70
  disability, total, defined, 70
  disease, occupational, 70
  epilepsy; accident caused by, 1860
  eye; detached retina not due to accident, 1121
  eye; loss of remaining eye, 1938
  hernia; strangulation of preexisting, 292
  lightning; compensability for death from, 1372
  medical fees; collection of, 292
  medical fees; jurisdiction of board, 292
  medical fees; jurisdiction of courts, 292

Medicolegal Abstracts—Continued
WORKMEN'S COMPENSATION ACTS—Continued
  medical fees; liability of employee, 292
  medical treatment; after sixty days period, 1772
  medical treatment; employer to furnish panel of physicians, 437
  medical treatment; physicians, selection of, 437
  medical treatment; physician's right to employ nurse, 1772
  medical treatment; refusal to accept, 1994
  notice of claim; injury believed trivial, 960
  notice of claim; mental and physical inability to give, 960
  nurse; employment of, 1772
  sacroiliac injury; trauma and infection, 1288
  tuberculosis not compensable injury, 70
  vaccination; death following, 1938

Society for Digestive and Metabolic Diseases, 1029
Society for Promotion of Graduate Instruction, Berlin, 1685
state, and U. S. Pharmacopeial convention, [Hirschfelder] 220—C
state, fracture exhibits by, 206
to promote graduate study among physicians, Essen, Germany, 217
Woman's Auxiliaries: See Woman's Auxiliaries
SODA, Baking: See Sodium bicarbonate
Caustic: See Sodium hydroxide
Chlorinated: See Chlorinated Soda
fountains, sanitation, Maryland, 1105
SODIUM acid phosphate and allergy, [Beckman] *1582
aluminum sulphate baking powder, effects, [Lyman] 753—ab
Amytal: See Amytal
bicarbonate, alkalization in acute diseases, [Achard] 1782—ab
bicarbonate, effects of prolonged use of, 1608
bicarbonate interferes with digestion, [Chiladrey] 1374—ab
bismuth thioglycollate, Thio-Bismol, 200
Cacodylate: Cacodylate, sodium
Chloride: See also Salt
chloride and water metabolisms, [Geréb] 308—ab
chloride, chlorination in acute diseases, [Achard] 1782—ab
chloride for high intestinal occlusion, [Doglotti] 456—ab
chloride inhalation, soreness of lungs from, 67
chloride metabolism in pneumonia, [Sabatini] 561—ab; [Scholz] 1627—ab
chloride solution (hypertonic) injection in thrombo-angiitis obliterans, [Ireland] 646—ab
chloride solution (hypertonic) intravenously for ileus, [Clément] 971—ab; [Schnohr] 1954—ab
chloride solution, intravenously, [Garrington] 1018—ab
chloride solution intravenously to overcome effects of loss of gastric juice, 936—E
chloride solution (physiologic) for irrigating empyema cavity, 886
chloride solution (physiologic) in anhydremia in burns, [Underhill] *852; 1430—E
chloride solution (physiologic) injections in pneumonia, [Sabatini] 561—ab
chloride solution, venoclysis, [Hendon] *1175
chloride solution, what strength to be used for varices? 1039
chloride treatment of bromide intoxication, [Harris & Hauser] *91; [Wiedman] 1281—C; [Goldenberg] 1689—C
Desoxycholate: See Bile salts
fluorescein, diagnostic value in meningitis, [Bonar] 1373—ab
fluoride vs. basal metabolism, [Goldenberg] 1782—ab
hydroxide, homogenization with, [Velicogna] 165—ab
hydroxide in blood sugar determination, [de Jongh] 978—ab
hydroxide poisoning alkali reserve in poisoning with, [Sécoulitch] 455—ab
hydroxide, reagent for demonstrating fungi in scalp hair, [Cornbleet] *1743
Hypochlorite: See Chlorinated Soda
in diet, [Stone] *713
Iodide: See Iodide
Iodoxy Quinoline-Sulphate: See Chiniofon
Isoamylethylbarbiturate: See under Amytal
morrhuate injection for simple ganglion, [McEvedy] 1781—ab
nitrate and sodium potassium iodide solution, rational way to give, 953
nitrate, effects, in powder manufacture, 1282
nitrite in seasickness, [Lebensohn] 1455—ab
potassium bismuthyl tartrate, 797
ricinoleate in bacterial hypersensitiveness of intestines, [Morris] 1862—ab
Salicylate: See Salicylate
sulphide reagent for demonstrating fungi in scalp hair, [Cornbleet] *1743
thiocyanate for essential hypertension, [Ayman] *247
Thiosulphate: See also Gold sodium thiosulphate
thiosulphate, can neoarsphenamine and sulpharsphenamine be dissolved in solution of? 1119

SODIUM—Continued
thiosulphate for cyanide poisoning, [Schmidt] 832—ab
thiosulphate to prevent iodine irritation of skin, [Jaffé] 459—ab
tungstate in blood chemistry analysis, [Matthieu] 1130—ab
2-oxo-5-iodo-n-acetate: See Iopax
"SOFTLITE," glasses to protect eyes from glare, [Coblentz] *593
SOIL, variations in, and vitamin content of foods, 1040
